NOTE ON SHELLES HROTI COSTA RICA KITCHENIMIDDEN, COLLECTED BY TIRS. WLINTAND BRANSEORD.

By W. II. DALE.

In their archæological explorations in Costa Rica, while examining the shell-mounds of Culebra near the western coast, a number of shells were obtained from the mounds to exhibit the species of which the shell-heaps were composed. They are, of course, in a semi-fossil condi-
tion and usually broken, but the following species have been identified :Phyllonotus nigritus Mensch., Strombus gracilior Sby., Arca grandis Brod., Chione dioncea Menke, Cardium procerum Sby., and Cardium consors B. \& S. These species, which formed part of the food-supply of the former inhabitants, are abundant in the fauna of the Gulf of Califorvia at the preseut day.

## ARSENTC ACID FOR PROTECTING ANATOMICAL PREPARATIONS EROM INSECTS.

By J. E. S. BACKSON, M. D.

Arsenic acid is most intensely strong, and comes in the form of a solid aud of a liquid, and the two are of about equal strength. Half an ounce (avoirdupois) of the one, or one-half of a fluid-ounce of the other, is to be added to a pint ( $f=x v j$ ) of soft water, and it is ready for use. Any membranous preparation that is to be distended and dried, as a portion of the alimentary canal, any of the hollow organs, an ovarian cyst, an aneurism, and many preparations that are not to be distended, will be most thoroughly protected, I believe, by the arsenical solution. A solution of corrosive sublimate will probably prove an equal protection; but the membrane, when dried, has a disagreeably opaque and ash-colored look, whereas, after the arsenical solution, it dries without any change. I cover the preparation fairly with the solntion, and leave it for about twenty minutes, then take it out, let it drain, then inflate or distend it, and, lastly, hang it up to dry.

Boston, Mass., February 19, 1878.

THE OCEANIU BONTTO ON THE COAST OF THEEUNHTEE STATES.

## By G. BROWN GOODE AHd TARLETON H. BEAN.

A speeimen of the Oceanic Bonito, Orcynus pelamys (Linné) Poey, was captured off Provincetown, Mass., in July or August, 1877, and taken to the Museum of Comparative Zoölogy by Mr. James H. Blake. The specimen was lent to the Fish Commission for study. Drawings have been made, and a table of measurements and description are here presented.

The specimen measures 447 millimetres ( 17.6 inches) to the end of the caudal carina. In form it closely resembles Orcynus alliteratus. The caudal rays are frayed, and their length cannot be exactly determined. The height of the body is a trifle more than one-fourth ( 0.26 ) of the length. The circumference of the body ( 0.71 ) is equal to the distance from suout to origin of anal ( 0.70 ). The length of the head $(0.30)$ is
