**Abstract** – A total of 349 epibenthic taxa of macroinvertebrates were recorded from 7 mainland and 15 island rocky intertidal sites in the Southern California Bight. The occurrence of these taxa among the 22 sites is presented as a checklist organized by phyla and classes. The majority of these were mollusks (188), followed by sponges (42) and crustaceans (30). Highest numbers of taxa were recorded from: Coal Oil Point (125); Big Fisherman's Cove, Santa Catalina Island (124); Santa Rosa Island (122); Willows Anchorage, Santa Cruz Island (122) and Government Point (120). Sites having the highest numbers of common taxa (*i.e.*, those whose average densities exceeded one individual per m<sup>2</sup>) were located on islands, and included: Willows Anchorage, Santa Cruz Island (38 taxa); Catalina Harbor, Santa Catalina Island (36); Prisoners Harbor, Santa Cruz Island (34); Frenchy's Cove, Anacapa Island (33); Cave Canyon, Santa Barbara Island (33) and Big Fisherman's Cove, Santa Catalina Island (33). The most abundant taxa (based on density and averaged over all sites) were *Chthamalus fissus/C. dalli*, followed by *Littorina keenae*, *Phragmatopoma californica* and *Tetraclita rubescens*. Based on percent cover, the most abundant taxa were *C. fissus/C. dalli*, *P. californica*, *Mytilus californianus* and *Anthopleura elegantissima*. With the exception of sponges, the number of northerly and southerly range extensions along the Pacific Coast recorded by this study were few.

## Introduction

Rocky intertidal community structure at a series of mainland and island sites in the

Southern California Bight was studied intensively between 1975 and 1979 as a part of a broad investigation of the Bight by the Bureau of Land Management (now Minerals Management Services) Outer Continental Shelf Program. Site records for the taxa of epibenthic macroinvertebrates from this 3-yr study are contained in individual chapters of the unpublished annual reports for the project (Littler 1978a, b, 1979). The main objectives of this paper are to: 1) integrate these disparate records and make them available in a concise format and 2) provide the data base for a biogeographic study of the rocky shore macroinvertebrates of the Bight (Seapy & Littler 1980), which was published as a part of the proceedings of the previous symposium on the California Islands (Power 1980).

A review of the existing literature on the invertebrate taxa of the Southern California Bight was completed by Bright (1974) prior to the initiation of the Outer Continental Shelf Program in 1975. Bright compiled species lists, which were arranged by major taxonomic groups. A useful aspect of these lists was the inclusion of habitat type for each species. A more thorough and taxonomically-current listing of invertebrate species from the Bight was compiled by Straughan & Klink (1980). This paper consisted of chapters on the various taxonomic groups written by specialists actively working on the invertebrates of the Southern California Bight. Unfortunately, species habitats were not included. Data on species abundances obtained at island sites before the inception of the BLM's Outer Continental Shelf Program are limited to the studies of Caplan & Boolootian (1967) at San Nicolas Island and Littler & Murray (1975) at San Clemente Island.

**Figure 1.** Location of the 22 rocky intertidal sites studied between 1975 and 1979 during the Bureau of Land Management study of the Southern California Bight.

No attempt is made here to review the literature concerned with specific studies on species of intertidal invertebrates from the Southern California Bight since two texts already have performed this task. Morris & co-authors (1980) presented synopses of the major species of rocky shore invertebrates from the California coast. Individual chapters of the book were written by specialists and each included a comprehensive list of literature citations. The classic text on rocky shore invertebrates of the Pacific coast, *Between Pacific Tides*, was revised by D. W. Phillips (Ricketts *et al.* 1985). The annotated systematic index in this book was thoroughly updated and includes the more recent literature from the Bight.

### Characterization of the Study Area

The Southern California Bight (Fig. 1) has been defined (Anon. 1973) as the open embayment of the Pacific Ocean bounded on the east by the North American coastline extending from Point Conception, California, to Cabo Colnett, Baja California, Mexico and on the west by the California Current. Eight islands are included within the Bight, four of which are northern (San Miguel, Santa Rosa, Santa Cruz and Anacapa Islands) and four southern (San Nicolas, Santa Barbara, Santa Catalina and San Clemente Islands). In terms of its topography, the Bight is a complex region, made up of basins delineated by submarine ridges, banks and islands.

### Characterization of the Study Area

The Southern California Bight (Fig. 1) has been defined (Anon. 1973) as the open embayment of the Pacific Ocean bounded on the east by the North American coastline extending from Point Conception, California, to Cabo Colnett, Baja California, Mexico and on the west by the California Current. Eight islands are included within the Bight, four of which are northern (San Miguel, Santa Rosa, Santa Cruz and Anacapa Islands) and four southern (San Nicolas, Santa Barbara, Santa Catalina and San Clemente Islands). In terms of its topography, the Bight is a complex region, made up of basins delineated by submarine ridges, banks and islands.

Cockerell (1939) was perhaps the first author to note that the region of the southern California islands, especially near the 4 northern islands, are remarkable for the impingement and mixing of both cold and warm waters. Santa Cruz and Santa Rosa Islands periodically are exposed to both cold and warm currents, while San Clemente and Santa Catalina Islands are bathed by relatively warm southern waters and San Miguel and San Nicolas Islands are exposed to the cold California Current throughout much of the year (discussed by Neushul *et al.* 1976; Seapy & Littler 1980). Seasonal

differences in the strength of the southward-flowing California Current (Wyllie 1966) and, concomitantly, counterclockwise flow of the Southern California Eddy (Fig. 2) contribute to the complex intermingling of physical conditions in the Bight. Zoogeographically, the islands in the Bight are intermediate between the cold-water and warm-water faunas to the north and south of Point Conception, with the offshore and northern islands having greater cold-water species affinities and the southern and nearshore islands having greater warm-water affinities (Seapy & Littler 1980).

**Figure 2.** Surface current flow in the Southern California Bight (after Seapy 1974). Long dashed lines represent mean geostrophic flow contours for the month of August, averaged over a 16 yr period Wyllie 1966). Short dashed lines indicate surface current flow during August 1969 (Kolpack 1971). Solid lines are surface currents derived from 10 m drogue releases during October 1958 (Scripps Institution of Oceanography 1962), while the single dotted line between Santa Rosa and San Nicolas Islands is based on Neushul & co-authors (1967).

**Table 1.** Sampling schedule between 1975 and 1978 at the 22 rocky intertidal sites in the Southern California Bight. Seasons were defined as May to August (Summer; S), September to November (Fall; F), December and January (Winter; W) and February to April (Spring; Sp).

## Materials & Methods

Rocky intertidal communities were sampled between July 1975 and April 1979 at 7 mainland and 15 island sites in the Southern California Bight (Fig. 1, Table 1). The latitude and longitude and a series of descriptive physiographic attributes that characterize each site are given in Table 2.

At each of the 22 sites, species abundances (density and percent cover) were determined from a minimum of 30, 0.15 m<sup>2</sup> rectangular quadrats, positioned at 1-m intervals along each of 2-4 transect lines (depending on the slope of the beach) that extended through the intertidal zone (described for each site in Littler, 1978a, b, 1979). Further details of the field methods are given in reviews of the first and second years of the study by Littler (1980a, b). Because density data were available from the quadrat samples, we were able to distinguish between those taxa at each site whose mean

densities were either greater or less than 1 m<sup>-2</sup>, averaged over all tidal intervals sampled and all seasonal site visits.

For the purposes of this study, macroinvertebrates are defined as conspicuous taxa, recognizable by the unaided eye in the field. Thus, small and cryptic animals such as the gammarid and caprellid amphipods were not included. In the field the macroinvertebrates were identified and enumerated in the quadrats. If a species identity was questionable, specimens were preserved in 10% sea water-formalin solution and subsequently identified by the senior author or outside taxonomic experts (see Acknowledgments). Two groups, the hydrozoans and bryozoans, generally were not identified to the species level. We could identify most specimens of hydroids only to the level of genus due to the lack of a taxonomic treatment of the group for the Pacific coast (Rees & Hand, 1975). Bryozoans are difficult

to identify, and none of the taxonomic experts on this group were available at the time to assist with the project. As a result most bryozoans, with the exception of those few species which the senior author could identify with reasonable confidence, were lumped together as either "erect" or "encrusting" forms. Finally, the highly mobile supratidal isopod *Ligia occidentalis* was not represented in any of the quadrat samples and was collected only sporadically as voucher specimens. Although this is a common species on rocky shores throughout the Bight, we have not included it here because the site records were so inconsistent.

In an earlier paper (Seapy & Littler 1980), we compared the faunal compositions of the islands in the southern California Bight to elucidate biogeographic patterns. The biogeographical classification for each species could not be included in that paper because of space constraints, but is included here. Taxa at each site were classified as either northern, southern, transitional or widespread. The ranges of northern and southern species frequently overlap in a region of about two and one-half degrees latitude centered at Point Conception, which Newman (1979) termed the Californian Transitional Zone (Fig. 3). Northern species are defined here as ranging northward from northern Baja California (at about Bahia del Rosario) into and often beyond the Oregonian Province. Southern species, on the other hand, range southward from central California (in the Monterey Bay area) into and, less commonly, through the Californian Province. Transitional species are narrowly defined as endemics restricted to the range of overlap, *i.e.*, between northern Baja California and central California (Fig. 3). Species classified as widespread range broadly to the north and south of southern California; at a minimum, through the Californian and Oregonian Provinces between central Baja California and northern California. The interested reader is referred further to the analysis of the biogeographic provinces and their latitudinal boundaries on the Pacific coast of

North America by Brusca & Wallerstein (1979).

A voucher collection of the macroinvertebrates from each of the study sites was assembled and deposited with the National Museum of Natural History, Smithsonian Institution, Washington, DC. A secondary voucher collection is archived at the Santa Barbara Museum of Natural History, Santa Barbara, CA.

## Results and Discussion

The macroinvertebrate taxa totaled 349 and are listed according to their respective phyla and classes in the Appendix. Most were mollusks (188), of which 149 were gastropods. Sponges were well represented (42 taxa), followed by crustaceans (30) and ascidians (25). The numbers of taxa belonging to the various phyla and classes at each site are summarized in Table 3. The highest numbers were recorded from: Coal Oil Point (125); Big Fisherman's Cove, Santa Catalina Island (124); Santa Rosa Island (122); Willows Anchorage, Santa Cruz Island (122); Government Point (120) and Dutch Harbor, San Nicolas Island (115). Government Point and Coal Oil Point were the only mainland sites with more than 100 total taxa. Considerable variability in the numbers of taxa occurred among the island sites, ranging from 61 at Crook Point, San Miguel Island to 124 at Big Fisherman's Cove, Santa Catalina Island. However, the variable sampling frequency at the study sites (Table 1) diminishes the relevance of these total counts.

For between-site comparisons, a more meaningful measure than total counts is the number of taxa whose densities were greater than  $1 \text{ m}^{-2}$ . Using this method, the highest numbers of taxa were all recorded at island sites (Table 3) and included: Willows Anchorage, Santa Cruz Island (38 taxa); Catalina Harbor, Santa Catalina Island (36); Prisoners Harbor, Santa Cruz Island (34); Frenchys Cove, Anacapa Island (33); Cave Canyon, Santa Barbara Island (33) and Big Fisherman's Cove,

**Table 2.** Physiographic attributes for the 22 rock intertidal sites. Water temperature categories are assigned on the basis of long term (10 yr) mean values from CalCOFI stations (Anon. 1963) as cold (<14.0°C), moderately cold (14.0-14.5°C), moderately warm (15.5-16.0°C) and warm (>16.0°C).

Santa Catalina Island (33). All other island sites and all of the mainland sites had 30 or fewer common taxa.

The three most abundant taxa from each site, in terms of both mean density and mean percent cover, are listed in Table 4. The barnacles *Chthamalus fissus/C. dalli* contributed the greatest density of all taxa at 16 of the 22 sites and ranked second or third at the remaining six sites. *Littorina keenae* was among

the top three taxa in terms of density at 10 sites, followed by *Phragmatopoma californica* (7 sites), *Tetraclita rubescens* (6), *Balanus glandula* (5) and *Macclintockia scabra* (4). On the basis of percent cover, the taxa that were most frequently represented among the top three at each site included: *C. fissus/C. dalli* (16 sites); *P. californica* (14); *Mytilus californianus* (8); *Anthopleura elegantissima* (7); *Tetraclita rubescens* (5) and *B. glandula* (4). It is

noteworthy that *T. rubescens* was among the top three taxa in terms of density and percent cover only at island sites.

The geographic ranges of the species recorded from the Bight are included in the Appendix. As we described earlier (Fig. 3 in Seapy & Littler 1980), the proportionate representation by species classified as "northern" increases going from the southern to the northern island sites, whereas an opposite trend

is seen for species characterized as "southern". Transitional species were represented more or less evenly at the various sites, although maximal percentages occurred at Anacapa and Santa Barbara Islands. These two islands would appear to be intermediate in terms of the mixing of cold and warm water faunas.

Comparisons of published geographic ranges of species with their occurrences among the sites in the Bight are noteworthy in a number

**Figure 3.** Zoogeographical provinces of the California and northern Baja California coast (after Seapy & Littler 1980).

of cases. Bakus & Green (1987) reported that 22 of 58 species of sponges collected at intertidal and subtidal sites in the Bight during the BLM sampling program represented new range extensions. However, there are few range extensions among the other invertebrate groups. The records of two species of sea cucumbers from this study represented substantial northward range extensions. *Pseudocnus californicus* was recorded here from Santa Barbara Island and West Point, San Nicolas Island, but its northernmost limits were reported previously to be Isla Santa Margarita in southern Baja California (M. Bergen, pers. comm.). We collected *Pachythylene lugubris* from Dutch Harbor, San Nicolas Island, while the northernmost limit of this species was previously considered to be

Cedros Island in central Baja California (M. Bergen, pers. comm.).

Several minor range extensions were noted among the molluscs. *Opalia funiculata* was reported by McLean (1978) to range from Santa Monica (south of Los Angeles) to Panama. We found this species to be widespread throughout the Bight, occurring at all of the mainland sites and many of the islands. The southernmost limits of three species included in Morris & co-authors (1980) are extended by the present records. *Tectura scutum* was reported to extend southward to Point Conception; we encountered it from Cuyler Harbor, San Miguel Island, Santa Rosa Island and at both sites on San Nicolas Island. Along the mainland, however, we did not find *T. scutum* at any site south of Government Point. *Nucella canaliculata* was listed as ranging from Alaska to central California (Cayucos). We recorded this species at our northernmost mainland site, Government Point. Finally, the southernmost limit of the chiton, *Tonicella lineata*, on the Pacific coast was given as San Miguel Island, and we recorded this species from Santa Rosa, Santa Cruz and San Nicolas Islands.

Because the sampling effort represented by this study was intensive and most of the taxa were identified to the species level, one would expect that a number of range extensions and possibly a few new species would have been discovered. Except for the sponges, this was not the case. The sponges represented the exception because the BLM baseline survey of the Bight was the first comprehensive survey of intertidal sponges from southern California (Bakus & Green, 1987).

#### Acknowledgments

Funding for this research was provided by the Minerals Management Services (formerly the Bureau of Land Management), U. S. Department of the Interior Contracts AA550-CT6-40, AA550-TF-44 and AA550-CT5-52. The manuscript was improved by the critiques

**Table 4.** Abundant taxa at the 22 rocky intertidal sites. Mean densities and cover values are averaged over the tidal range intervals sampled at each site and are listed for the three highest ranking taxa.

Study Area	Mean Density (n m <sup>-2</sup> )	Mean Cover (%)
<b>MAINLAND</b>		
Government Point	<i>C. fissus/dalli</i> (11,971) <i>L. keenae</i> (294) <i>A. elegantissima</i> (249)	<i>C. fissus/dalli</i> (10.1) <i>P. californica</i> (8.4) <i>A. elegantissima</i> (6.9)
Coal Oil Point (Goleta)	<i>C. fissus/dalli</i> (1,651) <i>Lacuna spp.</i> (1,255) <i>A. elegantissima</i> (412)	<i>A. elegantissima</i> (15.4) <i>M. californianus</i> (8.2) <i>C. fissus/dalli</i> (2.7)
Malibu	<i>C. fissus/dalli</i> (7,618) <i>M. californianus</i> (1,183) <i>L. keenae</i> (269)	<i>M. californianus</i> (29.2) <i>C. fissus/dalli</i> (8.1) <i>P. californica</i> (4.6)
Whites Point (Los Angeles)	<i>B. glandula</i> (582) <i>Mc. scabra</i> (336) <i>C. fissus/dalli</i> (238)	<i>B. glandula</i> (1.6) <i>A. elegantissima</i> (1.4) <i>S. purpuratus</i> (1.1)
Corona del Mar	<i>C. fissus/dalli</i> (408) <i>Mc. scabra</i> (59) <i>Pg. samuelis</i> (25)	<i>A. elegantissima</i> (1.0) <i>C. fissus/dalli</i> (1.0) <i>S. purpuratus</i> (0.5)
Dana Point	<i>C. fissus/dalli</i> (14,777) <i>L. keenae</i> (244) <i>P. californica</i> (78)	<i>C. fissus/dalli</i> (20.0) <i>P. californica</i> (1.0) <i>A. elegantissima</i> (0.5)

## Appendix

Individual site records for the 349 macroinvertebrate taxa arranged by phyla and classes. Ranges are indicated as northern (N), southern (S), transitional (T) or widespread (W); as defined in Materials and Methods. The 22 study site abbreviations are given in Table 1. Open circles indicate the presence of a given species or taxon at a given site and closed circles indicate that a species or taxon occurred at a mean density greater than  $1 \text{ m}^{-2}$  at that site.
