ADVERTISEMENT.

The scientific publications of the United States National Museum consist of two series, the *Proceedings* and the *Bulletins*.

The *Proceedings*, the first volume of which was issued in 1878, are intended primarily as a medium for the publication of original, and usually brief, papers based on the collections of the National Museum, presenting newly acquired facts in zoology, geology, and anthropology, including descriptions of new forms of animals, and revisions of limited groups. One or two volumes are issued annually and distributed to libraries and scientific organizations. A limited number of copies of each paper, in pamphlet form, is distributed to specialists and others interested in the different subjects as soon as printed. The dates of publication are recorded in the tables of contents of the volumes.

The *Bulletins*, the first of which was issued in 1875, consist of a series of separate publications comprising chiefly monographs of large zoological groups and other general systematic treatises (occasionally in several volumes), faunal works, reports of expeditions, and catalogues of type-specimens, special collections, etc. The majority of the volumes are octavos, but a quarto size has been adopted in a few instances in which large plates were regarded as indispensable.

Since 1902 a series of octavo volumes containing papers relating to the botanical collections of the Museum, and known as the *Contributions from the National Herbarium*, has been published as bulletins.

The present work forms No. 118 of the *Bulletin* series.

WILLIAM DEC. RAVENEL,

Administrative Assistant to the Secretary

In charge of the United States National Museum.

WASHINGTON, D. C., January 23, 1922.

PREFATORY NOTE.

In the annual report of the United States National Museum for 1900 (1902) there was published a descriptive catalogue of the collections of gems in the United States National Museum, as prepared by Mr. Wirt Tassin, then assistant curator in charge of the Division of Mineralogy, assisted by A. S. Eakle, subsequently professor of mineralogy in the University of California. As this catalogue has long been out of print, and as the collection has increased considerably since it appeared, a new edition has been decided upon. In this, however, a different method of treatment has been adopted, and the subject matter has been quite largely rewritten, so that it represents an essentially new work.

In order that just credit may be given to all concerned it may be well to state that the preparation of the catalogue was begun in 1916 by Dr. Edgar T. Wherry, then assistant curator in charge of the mineralogical collection. His resignation in 1917 caused a long delay, and meanwhile, during the occupancy of the building by the War Risk Bureau (October, 1917, to March, 1919), it was decided to entirely rearrange and recatalogue the collection which had been heretofore included with the general collection of minerals. This work, which involved as well the weighing and measuring of each individual stone, has been slow and laborious, but has been carried through in almost its entirety by Miss Margaret W. Moodey, the recorder for the department. In preparing the text so much of the edition of 1902 as was suitable has been retained (see particularly pp. 141-178), to which has been added the descriptive matter prepared by Doctor Wherry. Important additional matter is furnished in the accounts of the pegmatites and their associated minerals, that of southern California having been prepared by Dr. W. T. Schaller, for several years custodian of the collection. Other important additions are the references to the Gardner Williams collection of rocks from the diamond mines of South Africa, the list of gem names and the table for the identification of precious stones.

In addition to portraits of the founder and benefactor of the collection, and two colored plates illustrating gems in the collection, there have been added a number of plates showing typical localities from which gems are mined.

GEORGE P. MERRILL.

HANDBOOK AND DESCRIPTIVE CATALOGUE OF THE COLLECTIONS OF GEMS AND PRECIOUS STONES IN THE UNITED STATES NATIONAL MUSEUM.

By GEORGE P. MERRILL

Head Curator of Geology, United States National Museum

ASSISTED BY

MARGARET W. MOODEY AND EDGAR T. WHERRY

1. HISTORY AND ARRANGEMENT OF THE COLLECTION.

In 1884 Prof. F. W. Clarke, then honorary curator of the Division of Mineralogy, prepared an exhibit of American precious stones as a part of the United States National Museum's contribution to the New Orleans exposition. The same collection was displayed at the Cincinnati exposition in the following year, after which it was returned to Washington and incorporated in the mineral collection of the museum. From 1886 to 1890 the growth of the collection was steady though slow. In 1891 the greater part of the collection of precious stones made by Dr. Joseph Leidy, of Philadelphia, was purchased by the museum and combined with what was already on hand to form an exhibit for the World's Columbian Exposition at Chicago in 1893, the whole being returned to Washington when that exposition closed.

The great popularity of these collections, as attested by the number of visitors and their equally numerous queries, impressed upon the Museum authorities the advisability of extending the series and building it up systematically, a work which, though at once undertaken, proceeded at first slowly and with difficulty owing to the expense involved. Fortunately this has to a considerable extent been alleviated through the magnanimity of a private individual. The collections are still, however, poorly balanced, lacking a satisfactory showing of the rarer and more highly priced stones, a single one of which, of suitable size for exhibition, would consume the available income for an entire year. It is not too much to hope and expect that this discrepancy, like the last, may also be remedied through individual action.

In 1894 Mrs. Frances Lea Chamberlain bequeathed to the museum a collection of precious stones which had been assembled by her father, Dr. Isaac Lea (pl. 1). Her husband, Dr. L. T. Chamberlain (pl. 2), who subsequently (1897) became honorary curator of the collection, added a large number of specimens, and on his death bequeathed a sum of money, the income of which is to be used for their further increase.

In addition, many specimens have been received throughout this period as gifts from individuals and transfers from the United States Geological Survey. These various collections have been combined, and are now exhibited as "The Isaac Lea Collection," although the individual stones are differentiated by label. The exhibit at present is comprised in a row of table cases, extending down the center of the Mineral Hall. (See pl. 3.) At the west end of this row, immediately to the right of the entrance to the hall, stands a large group of amethyst crystals from Brazil. In table cases fronting the windows on the south side of the hall are other series illustrating the properties of precious stones, their appearance in the rough as contrasted with the cut form; gem minerals in the matrix or as occurring in nature, and artificial and imitation stones. Finally, an upright case between the windows at the center of the hall contains many semiprecious stones—that is, stones used in the manufacture of small ornaments, rather than for personal adornment.

It may be added that in building up the collection an attempt has been made to show the possibilities of commonplace material; that there is a goodly number of stones, in themselves of little intrinsic value, which when properly cut and mounted are not merely beautiful, but have the additional value of being out of the line of the usual material sold in shops. In this connection particular attention may be called to the cabochons of silicified wood, obsidian, epidotic granite (unakite), and green feldspar (amazonstone).

Leander J. Chacebloom

Who, in memory of his wife, Frances Lea, endowed the Isaac Lea collection in the United States National Museum.

2. NAMES AND PHYSICAL AND CHEMICAL PROPERTIES OF PRECIOUS STONES.

About 1,200 mineral species are now (1920) known to science, and of these somewhat less than one-tenth, or in round numbers 100, possess the properties of beauty and durability to such an extent that they are of importance, interest, and value as precious and semiprecious stones or gems. The present paper comprises descriptions of these minerals, lists of the cut stones of each represented in the collection, and notes on methods of identification, uses, etc. By way of introduction to the descriptive portion, brief definitions of the properties of the minerals and other explanatory notes are given; no attempt has been made, however, to make this a treatise on mineralogy, chemistry, or physics, and for further information concerning the various features discussed, reference should be made to works on those subjects.

Names.—The names of minerals have in part come down to us from the ancients, and in part been constructed by adding the suffix *ite* (from *ites*, similar to) or *lite* (from *lithos*, stone) to an appropriate root. As far as possible the names generally accepted by mineralogists have been adopted here.

Many stones, in addition to the standard names by which they are known to science, are also called by one or more synonyms, usually popular or trade names; the most important of these are added in each tabular description.

Chemical composition.—The chemical composition and formulas of the minerals are stated in a simple form. For the benefit of those unfamiliar with chemical terms it may be explained that the majority of mineral substances are compounds of two or more elements, in more or less definite proportions; and that these compounds are named by stating first the names of the elements forming the electro-positive or basic part of the compound, and then those of the elements forming the electro-negative or acidic part. The names of the negative elements are combined, usually in abbreviated form, and provided with significant suffixes, such as *ide* when a single element is concerned, and *ate* when oxygen is also present.

The formulas of the compounds are derived by placing the symbols of the elements together, with subscript figures to indicate the number of atoms of each represented. For definitions of the various chemical terms, and additional details, the reader is referred to textbooks of chemistry. The following table shows the elements that may be present in important amounts in precious stones, with their symbols:

Metals forming the bases of precious stones.

Aluminum.....	Al	Manganese.....	Mn
Barium.....	Ba	Mercury (<i>hydrargyrum</i>).....	Hg
Beryllium (or glucinum).....	Be	Nickel.....	Ni
Calcium.....	Ca	Potassium (<i>kalium</i>).....	K
Cerium.....	Ce	Sodium (<i>natrium</i>).....	Na
Chromium.....	Cr	Tin (<i>stannum</i>).....	Sn
Cobalt.....	Co	Titanium.....	Ti
Copper (<i>cuprum</i>).....	Cu	Uranium.....	U
Hydrogen.....	H	Vanadium.....	V
Iron (<i>ferrum</i>).....	Fe	Yttrium.....	Y
Lead (<i>plumbum</i>).....	Pb	Zinc.....	Zn
Lithium.....	Li	Zirconium.....	Zr
Magnesium.....	Mg		

Nonmetals forming the acid portions of precious stones.

Boron.....	B	Oxygen.....	O
Carbon.....	C	Phosphorus.....	P
Chlorine.....	Cl	Silicon.....	Si
Columbium.....	Cb	Sulphur.....	S
Fluorine.....	F		

Crystallization.—When a chemical compound passes from the liquid or gaseous state into the solid condition, cohesion and chemical affinity tend to draw its atoms together, and if these become grouped in a regular manner solids bounded by plane surfaces result; these are known as crystals. Six crystal systems (one of them consisting of two subsystems) are recognized, as follows: 1, Isometric, or cubic, comprising those crystals developed exactly alike in the six directions in space (front, back, right, left, up, and down), at right angles to one another; these have the general aspect of spheres, regularly flattened at an even number of equal intervals, and include the cube, regular octahedron, rhombic dodecahedron, etc., as well as combinations of these simple forms. 2, Tetragonal, comprising those crystals developed according to two different patterns, one repeated four times in directions at equal intervals in a plane, the other twice in the directions at right angles to that plane, all being at right angles to one another. The crystals of this system are made up of pinacoids, prisms, and pyramids. 3, Hexagonal, comprising crystals developed according to two different patterns, one repeated six times in directions at intervals lying 60° apart in a plane, and the other twice in the directions at right angles to that plane; the forms are like those of the tetragonal system. Trigonal (a subsystem of the hexagonal), comprising crystals developed according to two different patterns, one repeated three times at intervals lying 120° apart in a plane, and the other twice in the directions at right angles to that plane. 4, Orthorhombic system comprising those crystals developed according to three different

patterns, each repeated twice, in opposite directions, all again at right angles; the crystals of this system are made up of combinations of pinacoids, prisms, domes, and pyramids. 5, Monoclinic, system, comprising crystals developed like the orthorhombic, but with the patterns reappearing in one plane twice at angles less, and twice at angles greater, than right angles; the forms are like those of the preceding system. 6, Triclinic system, comprising crystals developed like the two preceding systems, but with none of the patterns repeated exactly at right angles to one another; the forms are essentially the same as those of the two preceding systems.

In addition, a few minerals have their atoms irregularly arranged, and consequently are without crystal form; to these the term amorphous is applied.

Color.—The color of an object expresses the character of the light reflected or transmitted by it. The principal terms used in describing it are: White, gray, black, violet, blue, green, yellow, red, and brown. There are also many intermediate hues, best described by a combination of terms, as blue-green, etc. Colors may be divided into two classes:

1. Essential or idiochromatic colors, due to the chemical elements which make up a compound. They are definite and characteristic for each substance and only disappear when it is decomposed. The principal elements yielding colors in the order of their most frequent occurrence in precious stones are:

Elements.	Valence.	Colors produced.
Iron.....	ferrous, Fe ⁱⁱ	green.
	ferric, Fe ⁱⁱⁱ	red, brown, yellow.
	both together.....	blue, black.
Chromium.....	chromic, Cr ⁱⁱⁱ	green, violet, red.
	negative, Cr ^{vi}	red, yellow.
Vanadium.....	V ⁱⁱⁱ and V ^v	red, brown, yellow.
Manganese.....	manganous, Mn ⁱⁱ	red, pink.
	manganic, Mn ⁱⁱⁱ	violet.
Copper.....	cuprous, Cu ⁱ	red.
	cupric, Cu ⁱⁱ	blue, green.
Titanium.....	titanic, Ti ⁱⁱⁱ	violet, blue.
Nickel.....	nickelous, Ni ⁱⁱ	green.
Cobalt.....	cobaltous, Co ⁱⁱ	red, blue.
Uranium.....	uranic, U ^{vi}	greenish-yellow.
Molybdenum.....	negative, Mo ^{vi}	yellow, red.
Neodymium.....	neodymic, Nd ⁱⁱⁱ	red-violet.
Cerium.....	cerous, Ce ⁱⁱⁱ	brown.

2. Nonessential or allochromatic colors, due to impurities or foreign constituents in a substance. They may vary widely from one specimen to another and may be of three different types: 1, Produced by evident, distinct particles, which in themselves show essential colors. Thus, finely divided ferric oxides are frequently inclosed in other

minerals, and render them yellow, brown, or red. 2, Disperse colors, due to submicroscopic inclusions, and varying with their shape, size, or arrangement. These colors are thought to have been developed, in part at least, by exposure in the earth to radio-active substances, slight decomposition having thereby been effected, and traces of the constituent elements set free. Heating usually destroys these colors, since it causes the free elements to reunite, but exposure to radiant energy of various kinds often restores them. 3, Internal reflection colors, due to symmetrically arranged inclusions, or to lamellae of extreme thinness, producing interference of light.

A special color phenomenon remains to be considered. Some minerals transmit light of different colors in different directions, and are said to be pleochroic. The most striking instance of this among precious stones is iolite, which is sometimes called "dichroite" because of this very property; in one direction it appears intense blue, in another somewhat paler blue, and in the third pale yellow. In many cases, however, the difference in color is less striking, and special means must be used in order to detect it. An instrument, called a dichroscope, is sometimes used for this purpose. It consists of a metal tube containing a cleavage piece of Iceland spar; at one end it is pierced with a small square hole, and at the other has a magnifying lens to serve as an eyepiece; the hole appears double when viewed through the latter. When a pleochroic stone is placed in front of the square hole, the two images of the hole will be differently colored.

Another method of observing pleochroism makes use of the polarizing nicol prism in the microscope. The stone is placed on the stage, and the polarizer introduced; the stone is observed in one position and again after turning the stage through 90° ; one of the pleochroic colors will be seen in each of these positions.

It should be noted that isometric minerals, which are isotropic between crossed nicols, show no pleochroism; tetragonal, hexagonal, and trigonal ones may show two colors, while those of the three remaining crystal systems in general show three colors.

Luster.—The luster or brilliancy of a mineral is a physical phenomenon connected with the manner in which light is refracted by it; the principal types are metallic, adamantine, and vitreous, but in addition some minerals of fundamentally vitreous luster possess certain peculiarities of structure, and as a result exhibit lusters resembling those of familiar substances, as waxy, greasy, silky, etc.

Hardness.—On the hardness of a mineral is dependent its resistance to scratching or abrasion. It is usually described by reference to a standard scale of 10 minerals, which are, beginning with the softest—1, talc; 2, gypsum; 3, calcite; 4, fluorite; 5, apatite; 6, orthoclase or microcline; 7, quartz; 8, topaz or beryl; 9, corundum (ruby or sapphire); and 10, diamond. Each of these will scratch all pre-

ceding in the series and be scratched by all following. In general only those minerals which possess a hardness greater than 6 in this scale—that is, which will at least scratch orthoclase—are sufficiently durable to be used as precious stones.

Specific gravity.—The specific gravity of a substance is its weight compared with an equal bulk of pure water; thus, the statement that diamond has a specific gravity of 3.5 means that it is three and one-half times as heavy as water. This property is characteristic of many precious stones and is of considerable value in their identification. It is determined by weighing the stone first in air and then suspended in water. The first weight, divided by the difference between the two, gives the value desired. For details as to the apparatus used for this purpose, books on mineralogy or physics must be consulted.

Optical properties. Index of refraction.—When light passes obliquely from one transparent substance to another, its direction is, in general, altered at their boundary. The well-known phenomenon of the apparent bending of a stick thrust into water is an illustration of this. The extent to which light entering minerals from the air is shifted is called their index of refraction; in mathematical terms this is the ratio between the sine of the angle of incidence and that of the angle of refraction. In amorphous minerals and in those crystallizing in the isometric system, the index of refraction is the same in all directions; in those crystallizing in the systems derived from a revolution ellipsoid—namely, the hexagonal, trigonal, and tetragonal—there are two different indices; and in those crystallizing in the remaining systems there are three. The last two groups are said to possess double refraction, which in the first is the difference between the two indices; in the second, the difference between the largest and smallest.

In a few minerals, notably in Iceland spar (transparent calcite), the double refraction is so strong that an object observed through the mineral appears double; in most cases, however, the double refraction is too slight to be rendered visible in this manner, and special means must be employed for its recognition; polarized light (light the vibration of which is limited to a definite plane) is generally used for this purpose. For details of the phenomena connected with polarized light, books on optical mineralogy must be consulted. It may be mentioned here, however, that it is most conveniently obtained by causing ordinary light to traverse prisms of Iceland spar so constructed that only one of the two rays into which the light is split is actually transmitted. The light emerging from such a prism (called a “nicol” after its inventor) is vibrating in a single plane; and if two nicols are disposed so that the planes are at right angles no light will be able to traverse the system. A substance with single

refraction placed between them is without effect on this extinction of the light and is said to be *isotropic*. But a substance possessing double refraction will, in all but one or two directions, cause light to be transmitted and is then described as *anisotropic*. The latter is also subdivided on the basis of number of optic axes (directions along which polarized light is not affected), crystals derived from revolution-ellipsoids having one such axis and being termed *uniaxial*, while those not so derivable have two and are termed *biaxial*. There is still another feature which is usually stated in connection with anisotropic crystals—the optical sign. When the greatest index of refraction is shown in the direction of the optic axis, in uniaxial crystals, or in the acute angle between the two optic axes in biaxial ones, the sign is described as plus (+); and in reverse case it is minus (-).

MINERAL HALL, UNITED STATES NATIONAL MUSEUM

3. DESCRIPTIVE CATALOGUE OF THE COLLECTIONS.

The arrangement of the gem names in this catalogue is alphabetical throughout so far as practicable. Under each mineral or gem is given in tabular form some of the more striking qualities of a descriptive or determinative nature, followed by remarks on the mode of occurrence and such other miscellaneous information as it is thought will be of value. In the catalogue proper the material is arranged in the following order: Name, locality, cut, color, weight, measurements, and catalogue number. The weights are given in the newly introduced metro-carats. The specimens are listed by localities, alphabetically, and under each locality are arranged in the order of decreasing weights, except where several stones are described together, these being placed at the end of the list for that particular locality.

Adularia.—See under Feldspar.

Agate.—See under Chalcedony.

Alabaster.—See under Gypsum.

Albite.—See under Feldspar (Moonstone).

Alexandrite.—See under Chrysoberyl.

Almandite.—See under Garnet.

Amazonstone.—See under Feldspar.

AMBER.

Synonym.—Succinite.

Composition.—A resinous substance, containing carbon, hydrogen, and oxygen.

Crystallization.—Amorphous.

Color.—Yellow, orange-yellow, brown-yellow, or rarely red.

Luster.—Resinous; transparent to translucent.

Hardness.—2.5; too soft for extensive use as a precious stone.

Optical properties.—Mean refractive index 1.54; is isotropic excepting when in a condition of strain.

Specific gravity.—1.07; noticeably light.

Amber is a poor conductor of heat and electricity, becoming electrified when rubbed on cloth so that it will attract small bits of paper. It can be distinguished from imitations such as rosin and celluloid by being less inflammable, though it burns readily with a rich yellow flame, yielding an aromatic odor. Heated to 150° C. it begins to soften and melts at about 250°. From most minerals it may be distinguished by its extreme lightness and its solubility in alcohol.

It occurs in sediments of the later geological periods, representing the fossil resin of the tree *Pinus succinifera* and other plants; sometimes contains insects which became embedded in the material while it was soft and in a pitch-like condition. It is used chiefly for beads, earrings, and other similar ornaments. The value of the crude material is but a few cents an ounce.

LIST OF SPECIMENS.

COAST OF THE BALTIC SEA.

Two cuff buttons; pale yellow; opaque.....	No. 674
Breastpin of 3 faceted beads and pendant; light yellow-brown.....	No. 675
Necklace of 50 faceted beads: light yellow-brown.....	No. 676
Bracelet of 16 rectangular links, 20 by 15 mm. average size, and buckle; alternating pale yellow and clouded amber. Isaac Lea collection.....	No. 1641

INDIA (BURMA).

--	---------

Amethyst.—See under Quartz.

ANDALUSITE.

Variety.—Chiastolite or macle.

Composition.—Aluminum orthosilicate, $Al_2O(SiO_4)$.

Crystallization.—Orthorhombic.

Color.—Gray when pure; often showing brown-green, or yellow-green, and rarely brown, pink, or violet hues, owing to the presence of impurities of unknown nature; rather strongly pleochroic, green to yellow or even to red.

Luster.—Vitreous; transparent to translucent.

Hardness.—7.5; a durable stone.

Specific gravity.— 3.20 ± 0.05 .

Optical properties.—Mean refractive index, 1.64; double refraction moderate, 0.01; biaxial, negative.

Chiastolite contains symmetrically arranged carbonaceous matter yielding in polished specimens a black cross on gray background. It may be distinguished from tourmaline and other similar minerals by its pleochroism, specific gravity, and optical properties. It occurs in metamorphic rocks, especially mica schist.

Uses.—Clear andalusite is cut faceted; chiastolite is cut cabochon and used for scarfpins, and ranks as a curiosity rather than a gem.

LIST OF SPECIMENS.

BRAZIL.

Step brilliant, rectangular girdle; brown-green; 1.39 carats; 11 by 6 by 3 mm.....	No. 568
Brilliant, rectangular girdle; dark green; 1.03 carats; 7 by 6 by 4 mm.....	No. 566
Step, rectangular girdle; brown-green; 0.83 carat; 10 by 4.5 by 2 mm.....	No. 569
Step brilliant, square girdle; brown-green; 0.72 carat; 6 by 3.5 mm.....	No. 567

Aquamarine.—See under Beryl.

Aragonite.—See under Calcite and Aragonite.

AXINITE.

Composition.—Iron calcium aluminum hydrous boro-silicate, $\text{FeCa}_2\text{Al}_2(\text{OH})(\text{BSi}_4\text{O}_{15})$.

Crystallization.—Triclinic; habit wedge-shaped.

Color.—Brown; sometimes violet, violet-brown, or yellow-brown; essential, due to the iron, and to manganese which may replace it; strongly pleochroic, green to brown to blue.

Luster.—Brilliant-vitreous; transparent.

Hardness.—6.5; a fairly durable stone.

Specific gravity.— 3.30 ± 0.05 .

Optical properties.—Mean refractive index 1.68; double refraction weak, 0.009; optically biaxial, negative.

Axinite may be distinguished from tourmaline and other similar minerals by its pleochroism, specific gravity, and optical properties. It occurs in veins, chiefly in metamorphic rocks and is in little demand as a precious stone, because of unattractive colors and brittleness. Value purely arbitrary.

LIST OF SPECIMENS.

FRANCE (DAUPHINÉ).

Step-brilliant, square girdle; violet-brown; 1.59 carats; 7.5 by 4.5 mm....	No. 581
---	---------

AZURITE.

Composition.—Hydrous copper carbonate, $\text{Cu}_3(\text{OH})_2(\text{CO})_2$.

Crystallization.—Monoclinic.

Color.—Dark blue, characteristic of many compounds of copper.

Luster.—Vitreous; translucent to opaque.

Hardness.—4; too soft for extensive use as a precious stone.

Specific gravity.— 3.80 ± 0.05 .

Optical properties.—Mean refractive index 1.9; double refraction very strong, 0.20; biaxial, positive.

The mineral dissolves readily in hydrochloric acid with effervescence to a yellow solution. It may as a rule be distinguished from other blue precious stones by its intense color, softness, and solu-

bility. It occurs in veins and pockets and has been derived from sulphide ores through decomposition by surface water, as has malachite, with which it is very commonly associated. Used for ornaments, scarfpins, etc.; the value as a gem is little more than the cost of cutting. (See under Malachite.)

BENITOITE.

Composition.—Barium titanate-silicate, $BaTiSi_3O_9$.

Crystallization.—Hexagonal (trigonal), holohedral.

Color.—Pale to deep blue; pleochroic.

Luster.—Vitreous.

Hardness.—6.5.

Specific gravity.—3.64—3.67.

Optical properties.—Refractive index 1.757 to 1.804. Double refraction strong and positive. High index of refraction and marked pleochroism are distinguishing features of the mineral. So far as at present known it occurs only in natrolite veins cutting serpentine. It is usually cut as brilliant, more rarely cabochon. A limited supply of this mineral has as yet been found (pl. 4). It is, therefore, little used, though of good quality.

LIST OF SPECIMENS.

UNITED STATES.

California.

San Benito County:

Two gems, brilliant, circular girdle; blue and violet blue; 0.95 and 0.87 carats, 5.7 by 4.5 and 5.5 by 4 mm. Isaac Lea collection No. 1180.

BERYL.

Varieties.—Common, aquamarine, emerald, morganite (vorobievite), and golden beryl.

Composition.—Beryllium aluminum metasilicate, $Be_3Al_2(SiO_3)_6$.

Crystallization.—Hexagonal; habit usually prismatic, rarely tabular.

Color.—Colorless when pure; often showing green, blue, yellow, or pink hues, and in part named accordingly: Pale blue, green-blue, or blue-green, aquamarine; intense green, emerald; yellow, orange-yellow, or brown-yellow, golden-beryl; and pink, morganite, or vorobievite. Slightly pleochroic, if deeply colored.

Luster.—Vitreous; transparent.

Hardness.—8 (less when altered); a durable stone.

Specific gravity.— 2.75 ± 0.10 .

Optical properties.—Mean refractive index 1.58; double refraction weak, 0.005; uniaxial, negative. With the microspectroscope emerald yields two absorption bands in the orange, which form a characteristic distinction from green tourmaline, green corundum,

BENITOITE MINE, NEAR SAN BENITO, CALIFORNIA

and imitation emerald (green glass). Other varieties of beryl show no spectrum. Other distinctive characters are color, slight pleochroism, specific gravity, refractive index, and weak double refraction.

Beryl occurs chiefly in granitic pegmatites and related formations. The famous emerald deposits of Muzo, Colombia, South America, are in a limestone thought to have been metamorphosed by solutions accompanying the intrusion of pegmatite dikes. All the transparent varieties of beryl are of more or less value as precious stones; they are usually cut faceted. The emerald is considered of greatest value, though many of the aquamarine varieties are of great beauty.

BERYLLONITE.

Composition.—Sodium beryllium phosphate, NaBePO_4 .

Crystallization.—Orthorhombic.

Color.—Colorless.

Luster.—Vitreous; transparent.

Hardness.—6; not very durable.

Specific gravity.— 2.85 ± 0.05 .

Optical properties.—Mean refractive index, 1.56; double refraction moderate, 0.01; optically biaxial, negative.

The mineral can be distinguished with certainty from other precious stones which resemble it only by chemical tests. It occurs in pegmatite, like beryl and tourmaline, and was first discovered among the

disintegrated material of a granitic vein at Stoneham, Maine. It is not much used as a precious stone and is cut chiefly as a matter of scientific interest.

Bloodstone.—See under Chalcedony.

CALAMINE.

Composition.—Basic zinc metasilicate $(\text{ZnOH})_2(\text{SiO}_3)$.

Crystallization.—Orthorhombic; hemimorphic; habit usually columnar-radiated.

Color.—White when pure, but often green or blue owing to the presence of admixed copper carbonates.

Luster.—Vitreous or somewhat silky; translucent.

Hardness.—5; not very durable.

Specific gravity.— 3.45 ± 0.05 .

Optical properties.—Mean refractive index 1.62; double refraction strong, 0.02; optically biaxial, positive.

Calamine may be distinguished from most other minerals which resemble it by softness and solubility, being readily attacked by dilute hydrochloric acid, with the formation of gelatinous silica. From smithsonite, which is likewise attacked, it is distinguished by lack of effervescence. It occurs as an alteration product of sulphide zinc ore in deposits above the permanent water level and it is sometimes cut cabochon and used for scarfpins, etc., but the value little exceeds the cost of cutting.

LIST OF SPECIMENS.

MEXICO (DISTRICT OF GALEANA, SIERRA MADRE, GUERRERO).

Cameo.—See under Calcite and Aragonite (shell cameo), and Quartz, variety Onyx.

Carnelian.—See under Chalcedony.

Catalinite.—See under Quartz.

Cat's-eye.—See under Chrysoberyl and Quartz.

CHALCEDONY.

Varieties.—Here are included the crypto-crystalline and amorphous, often more or less impure, varieties of silica comprised under the names agate, bloodstone, carnelian, chrysoprase, jasper, prase, etc. The term agate includes the banded forms (fig. 2); carnelian, the red; chrysoprase, the green; bloodstone, a compact, dark, opaque variety with blood red spots; jasper, a great range of opaque impure forms of a red, yellow brown, or black color, the varying hues being due mainly to iron and manganese oxides. The silicified wood of the Arizona "Fossil Forest" is largely chalcedony in the crypto-crystalline form of jasper; onyx is a variety of agate with straight alter-

FIG. 2.—BANDED AGATE.

nating bands of light and dark; moss agate, a milky or colorless form with dendritic markings of manganese oxide resembling moss or other plant growth. Plasma and prase are green in color, and sard, or sardonyx, of a golden to blood red color.

These stones are cut only cabochon or flat, un-faceted forms, and are valued according to their varying beauty, common agate and jasper being the cheaper forms. The majority of agates sold in the shops are from Brazil, and are cut and artificially colored in Germany.

The moss agates of Wyoming are found, according to Mr. C. J. Hares, of the United States Geological Survey, scattered over the surface of the ground in several townships of Fremont County and along the Sweetwater Valley. The agate pebbles range in size from 2 inches or more in diameter and are usually well rounded. The good specimens are uncommon, being associated with a great many

worthless pebbles such as black and red jaspers, quartzite or white milky quartz, or chalcedony. The agates range from an opaque white and gray to highly translucent gray with black, dark brown, reddish to yellow-brown dendritic markings. Those with the black and dark brown markings are the most common. They show great variation in size and delicacy of pattern. Some are small rounded tufts, too dense to show individual lines, and others are as much as 2 or 3 millimeters across, exhibiting very delicate moss-like or seaweed-like markings. The original source of the gravel is supposed to have been the White River formation of the vicinity, which is of Oligocene age. (See further under Quartz.)

LIST OF SPECIMENS.

CHALCEDONY, common.

GERMANY.

Two gems, cabochon, one rectangular, one elliptical; pale cloudy gray; 41 by 29 by 5, 19 by 16 by 6 mm. Gift of George F. Kunz..... No. 803

Chlorastrolite.—See under Prehnite.

CHROMITE.

Composition.—Ferrous chromite, FeCr_2O_4 .

Crystallization.—Isometric; habit octahedral; usually massive.

Color.—Black; streak pale brown.

Luster.—Sub-metallic.

Hardness.—5.5; rather soft for use as a precious stone.

Specific gravity.— 4.5 ± 0.2 .

Optical properties.—Refractive index extremely high; practically opaque.

Methods of identification.—Distinguished from jet by its heaviness; from hematite by its streak.

The mineral occurs in serpentinous rocks, and often accumulates as a "chrome sand" in the beds of streams flowing over such rocks.

It is used rarely for beads and similar objects, being cut mostly only as a matter of scientific interest; value not exceeding the cost of cutting.

LIST OF SPECIMENS.

CANADA (THETFORD).

One double cabochon, four cabochon, circular girdle; black, polished; 1.435 grams; 6 mm. average diameter. Isaac Lea collection..... No. 679

CHRYSOBERYL.

Varieties.—Alexandrite; cat's-eye or cymophane.

Composition.—Beryllium aluminate, BeAl_2O_4 .

Crystallization.—Orthorhombic; habit tabular.

Color.—Pale yellow, green-yellow, yellow-green, dull green, and rarely brown-yellow or orange-brown; in artificial light, red, especially in the emerald green variety alexandrite; pleochroic, green to red, in deep colored varieties.

Luster.—Vitreous; in cat's-eye, silky.

Hardness.—8.5; a very durable stone.

Specific gravity.— 3.60 ± 0.1 .

Optical properties.—Mean refractive index 1.75; double refraction moderate, 0.01; optically biaxial, positive.

The variety cymophane, the true cat's-eye, shows minute laminations which yield a peculiar luster. Alexandrite shows with the microspectroscope a strong absorption band in the yellow and can be recognized by the red color in artificial light; pale colored varieties, including cat's-eye, can be distinguished from similar minerals by the high specific gravity and by optical properties. The mineral occurs in pegmatite and in mica gneiss. The chief commercial sources of chrysoberyl are Brazil and Ceylon. The variety alexandrite comes chiefly from the Takovaya stream in the Ekaterinburg district of Russia, though it has more recently been found in Ceylon. The mineral "was discovered in Russia on the very day on which the coming of age of the Czarevitch Alexander Nicolajevitch, afterwards Czar Alexander II, was celebrated, and in his honour it was named by the Finnish mineralogist Nils von Nordenskiöld."

Stones resembling chrysoberyl have been produced artificially, but their complete identity with the natural mineral remains to be proved. The peculiar property shown by alexandrite of changing color in artificial light renders it rather highly prized as a gem; cat's-eye is usually cut cabochon so as to bring out the luster.

CHRYSOLITE.

Synonyms.—Olivine, peridot.

Composition.—Magnesium orthosilicate, Mg_2SiO_4 .

Crystallization.—Orthorhombic.

Color.—Yellow-green, green-yellow, or rarely pure yellow; essential, due to ferrous iron replacing magnesium; very faintly pleochroic.

Luster.—Vitreous.

Hardness.—6.5; a fairly durable precious stone.

Specific gravity.— 3.40 ± 0.2 .

Optical properties.—Mean refractive index, 1.68; double refraction strong, 0.03; optically biaxial, positive.

Chrysolite, also known under the names olivine and peridot, is an abundant constituent of many igneous rocks, as the basalts, peridotites, and stony meteorites, but in most cases in the form of small granules only. When these rocks become disintegrated, the mineral, which is very refractory to weathering agencies, is set free and accumulates in the residual sand. The principal American sources are the Navajo Indian country of Arizona, and New Mexico. (See pl. 5.)

ALLUVIAL SAND CARRYING CHRYSOLITE, NAVAJO INDIAN RESERVATION, ARIZONA.

CORAL.

Corals are composed of calcium carbonate and are formed as stony secretions within the body of the coral polyp. Of the many varieties known only those formed by the *Corallium rubrum* from the African coast of the Mediterranean are utilized for gem purposes. The material is dredged from a depth of 500 to 800 feet by means of metal dragnets. The colors vary from deep red through pink to greenish, brown, yellow, white, and black. The white, pink, and red varieties are utilized chiefly in the form of necklaces and bracelets.

Small chain of beads, red.....	No. 1516
Two roses, red.....	Nos. 1517, 1518
Twenty-two spherical beads, white, 3 circular beads, pink; 4 rings, 5 leaf shaped, and 36 small branching pieces, red. Gift of H. P. Petersen.	Nos. 1843, 1844, 1845

CORUNDUM.

Varieties and synonyms.—Ruby, sapphire, oriental amethyst, oriental emerald, and oriental topaz.

Composition.—Aluminum sesquioxide, Al_2O_3 ; the aluminum may be partially replaced by chromium, iron, titanium, etc., yielding colored varieties.

Crystallization.—Hexagonal-trigonal, rhombohedral; habit usually pyramidal, with rounded edges, and with prominent basal plane. (See fig. 4.)

Color.—Colorless when pure; often showing more or less intense coloration, and named accordingly; ruby, the red variety colored by chromium; sapphire, blue, titanium; oriental amethyst, violet, chromium and titanium; oriental emerald, green, iron and titanium; and oriental topaz, yellow, iron. May also show silvery internal reflections, usually in the form of a six-rayed star, owing to symmet-

FIG. 4.—CORUNDUM CRYSTALS.

rically arranged inclusions (asteria); pleochroic from pale to deep tints.

Luster.—Rather dull and greasy in natural state; adamantine when cut; transparent to translucent.

Hardness.—9; will scratch every mineral except diamond; extremely durable.

Specific gravity.— 4 ± 0.1 ; noticeably heavy.

Optical properties.—Mean refractive index, 1.76; double refraction weak, 0.008; uniaxial, negative.

The transparent corundums rank among the most valuable of gem stones, and include two recognized varieties, the red ruby and the blue sapphire. The ruby varies in hue from a rose to a deep carmine, the

same crystal occasionally exhibiting different colors, the most approved tint being a "pigeon's blood" red. The sapphire, in general, includes corundums of any color except the red. Specifically, the name is limited in its use to the blue-colored specimens, the approved tints being royal blue, velvet blue, and cornflower blue. The sapphire occasionally exhibits a different color effect by natural light from that seen by artificial light, and as a rule is less brilliant by the latter.

Corundums of other colors are named according to their hues: Oriental emerald, the green-colored kinds, varying in tint from a lively green, exceeding that of the emerald, to a sea or blue-green. Oriental amethyst, purple or amethystine. Oriental topaz, yellow, rivaling the yellow diamond in brilliancy. Oriental hyacinth is hyacinthine in tint and is rare. Adamantine spar includes the hair-brown varieties.

The six-rayed star seen in many clouded corundums, especially when cut cabochon with the summits cutting the vertical axis of the prism, is due to numerous minute crystals or layers within the stone which reflect the incident light so as to produce the stellar effect. These rays are invariably white, though the specimen may be of any color, and may be best seen by artificial light. This chatoyancy, when marked, gives the asteria, or star stone, also known as the star ruby or star sapphire, as the case may be. Should the gem assume a fibrous texture, the chatoyancy affords the "cat's-eye" ray.

Corundum is associated with crystalline rocks as granular limestone or dolomite, gneiss, granite, mica, and chlorite schist. The finest sapphires are usually obtained from the beds of streams, either in modified hexagonal prisms or in rolled masses, accompanied by grains of magnetic iron ore and other heavy minerals.

The best rubies come from the mines of upper Burma, in an area about 30 miles square, of which Mogok is the center, where they are found in place in crystalline limestone; they occur also in gravel and in the soil of the hillsides. A similar locality exists in the marble hills of Sagyin, 16 miles north of Mandalay. Ruby mines have also been worked at Jagdalik, near Kabul, Afghanistan. Blue sapphires are brought from Ceylon.

The great corundum region of the United States extends from the Virginia line through North and South Carolina, across Georgia and into Alabama. Numerous localities are known in the crystalline rocks of the region, especially in Madison, Buncombe, Haywood, Jackson, Macon, and Clay Counties, North Carolina. Rubies rivaling those from Burma in color have been found in the Cowee district of this State, but the region affords no commercial supply. Fine gem sapphires are found on the river bars in the Upper Missouri near Helena, Montana. They are most abundant at Eldorado Bar, French-

mans Bar, and Yogo Gulch, where they occur in a pyroxenite and as pebbles more or less rolled in the sands resulting from its disintegration. The Montana gems rarely exceed one-fourth to one-half inch in length and range in color from light green, light blue, steel blue, bluish red, light red, and intermediate shades; frequently the colors mentioned will appear red or assume a reddish tinge by artificial light. They are usually dichroic and often blue in one direction and red in another. (See pl. 6.)

Rubies of a high degree of perfection are now produced artificially and their manufacture has become a matter of trade importance. The artificial stone, in crystallization and composition, is identical with the natural.

CORUNDUM, variety RUBY.

CROCIDOLITE.

Crocidolite, also known as "Tiger Eye," is a fibrous, asbestiform mineral which in many cases, through the oxidation of the iron and an infiltration of silica, has become altered into a hard, compact siliceous stone, with often a beautiful chatoyant play of colors, and is much used in cheaper forms of jewelry. The source is South Africa.

LIST OF SPECIMENS.

UNION OF SOUTH AFRICA (GRIQUALAND WEST).

Necklace of 56 round beads; brown; 7 to 4 mm. diameter. Bequest, William H. Forwood.....	No. 1547
Cabochon, elliptical girdle; light brown and white; 64.5 carats; 44 by 33 by 5 mm. Gift of George F. Kunz.....	No. 1453
Cabochon, circular girdle; brown; two gems, 17.57 and 17.37 carats; 17 by 8, 20 by 5 mm. (fig. 7, pl. 7).....	No. 1455
Cabochon, elliptical girdle; brown; two gems, 14.86 and 14.42 carats; 24 by 17 by 5 mm. Isaac Lea collection.....	No. 1454
Cabochon, circular girdle; green; 12.5 carats; 17 by 6 mm.....	No. 1456

Cabochon, circular girdle; brown; 5.74 carats; 11 by 7 mm.....	No. 1457
Cameo; elliptical girdle; brown; 5.025 carats; 14 by 10 by 5 mm.....	No. 1458
Cabochon, elliptical girdle; brown; 2.025 carats; 12 by 6 by 4 mm.....	No. 1452
Cabochon, elliptical girdle; two gems, one brown, one green; 1.49 and 1.42 carats; 9 by 6 by 4, 10 by 5 by 4 mm.....	No. 1458

Demantoid.—See under Garnet.

DIAMOND.

FIG. 5.—DIAMOND CRYSTALS. SHOWING CHARACTERISTIC FORMS.
(Enlarged 6 diameters.)

From Gardner F. Williams collection.

Composition.—Carbon (isometric form), C.

Crystallization.—Isometric, holohedral; habit usually octahedral, with rounded edges; cleavage, octahedral (fig. 5).

Color.—Colorless when pure; often showing nonessential violet, blue, green, yellow, brown, or red colors, owing to the presence of traces of impurities of unknown nature.

Luster.—Rather dull and greasy in the natural state, brilliantly adamantine when cut; when free from flaws, transparent.

Hardness.—10; will

scratch every other known mineral; the most durable of precious stones.

Specific gravity.— 3.52 ± 0.02 noticeably heavy.

Optical properties.—Refractive index, 2.42; isotropic in polarized light, or slightly anisotropic if under strain; dispersion of spectrum colors very high.

Miscellaneous properties.—A rather good conductor of heat so that it feels cold when placed against the skin (in a sensitive spot).

Occurrence.—Occurs in ultra-basic igneous rocks and in gravels derived by their disintegration. (See Williams collection of rocks from the diamond mines of South Africa, p. 135.)

Artificial production.—Made by Moissan by the sudden chilling of molten iron containing dissolved carbon; has also been made by other processes involving simultaneous action of high temperature and pressure.

The diamond is the hardest of gems; is the only one that is combustible; is the most highly refractive; and surpasses all others in the property of dispersing light—that is, dividing light into colored rays, causing that peculiar flash of prismatic hues called its fire. The cleavage of the diamond is highly perfect and parallel to the octahedral faces. The luster, especially of artificial faces, is peculiarly brilliant and is superior to that of any other gem. The remarkable brilliancy of the diamond results in part from the total reflection of light from its internal faces when the incident ray strikes it at an angle of a little more than 24 degrees. The stone also refracts light strongly. To the refractive and dispersive power of the diamond is due the flash of colors or fire, characteristic of the stone, the colorless specimens exhibiting it to the greatest degree; the colored to the least, or not at all.

The range of color of the diamond is extensive, including nearly all the prismatic hues. The whites, yellows, and browns perhaps afford the greatest number of shades and are the most numerous. Next to these, for colored specimens, the greens, including all shades, are most plentiful; the pure grass-green and emerald-colored stones are, however, very rare, as, indeed, are all the strongly colored specimens. Red stones of strong, rich, deep tints are extremely rare; so, too, are the garnet, hyacinth, rose-red, peach-blossom, and lilac-colored specimens. Practically all of the blue stones known have been found in India, and their occurrence is as rare as the red. Cinnamon, brown, black, milky, and opalescent stones are occasionally met with. Pure colorless diamonds without a flaw or tint of any kind are more rare than is generally supposed.

In diamonds, perfectly white stones or decided tints of red, rose green, or blue are most highly prized. Fine cinnamon, salmon, brown, black, or yellow stones are also much esteemed. When flawless and without tint of any kind they are termed "first water." If they possess a steely-blue color they are called "blue white." It is impossible to estimate the value of a diamond by its weight. Color, brilliancy, cut, and general perfection of the stone are all to be considered. Of two stones, both flawless and of equal weight, one may be worth twice the other. Off-colored or defective stones may sell at carat prices regardless of size, while the value of an ordinary good water stone increases in an increasing ratio with its weight up to about 20 carats, beyond which no rule holds good. Exceptionally perfect stones have no fixed value, the price depending upon the purity and brilliancy and, of course, the condition of the market.

Among the historically interesting diamonds are the "Regent" or "Pitt" diamond, weighing $136\frac{3}{4}$ carats, for many years the finest large diamond in the world. It was discovered in India in 1701, and weighed 410 carats in the rough. The finest blue diamond is the

"Hope," an almost sapphire-blue stone, weighing $44\frac{1}{2}$ carats. The "Dresden Green" is the finest green diamond, a pear-shaped $48\frac{1}{2}$ -carat brilliant. The "Orloff," a 193-carat stone, was in the scepter of the Emperor of Russia. The Russian treasury also contained the "Shah," an 86-carat stone. The "Koh-i-Nur," or "mountain of light," which weighed, when first brought to England, $186\frac{1}{16}$ carats, but was reduced by recutting in 1852 to $106\frac{1}{16}$ carats, is among the English crown jewels. The "Victoria," a Cape diamond, weighed $457\frac{1}{2}$ carats in the rough and 180 carats cut. The world's largest diamonds, the "Excelsior" and the "Cullinan," weighing in the rough, respectively, 199.04 grams (995.2 carats) and 621.2 grams (3,106 carats), are both South African, the former being found in 1893 and the latter in 1905. These have both been reduced in size by cutting, and glass models of some of the resultant stones are included in the collection of imitation stones. The largest diamond in America at the present time and the finest yellow diamond in the world is the "Tiffany," a flawless double-cut brilliant of a rich orange-yellow color. It was found in South Africa and weighs $125\frac{3}{8}$ carats.

Before the discovery of the Brazilian and African mines all diamonds were brought from India and Borneo. In India the diamond is met with at three principal localities. The first is in southern India, in the Madras Presidency, and embraces the districts of Kadapah, Bellary, Karnul, Kistna, and Godavari. This region includes the famous "Goleonda" district, the name, however, being not that of a mine, but merely the general term for the market where diamonds were bought and sold. The second locality is farther north and includes a large tract between the Mahanadi and Godavari Rivers; it embraces Sambalpur and Waigarh, 80 miles southeast of Nagpur, as well as portions of the Province of Chutia Nagpur. The third region is in Bundelkhand, in central India, the principal working being near the city of Panna. The Indian diamonds were obtained in part from alluvial deposits and in part from a quartzose conglomerate; at Panna this conglomerate appears to be largely made up of fragments of a lower sandstone, which it has been suggested may represent the original matrix. The yield of the Indian mines, once so large, is at present very small. The principal Borneo locality is in the basin of the Kapoeas River, on the west side of the Ratoos Mountain, near the town of Pontianak.

The diamond deposits of Brazil were discovered in 1728 and were at one time very productive, although the yield is at present small. Near Diamantina in Minas Geraes the diamonds are obtained in part from river washings and in part from prairie washings. The river deposits consist of rolled quartz pebbles, mixed with or united by a ferruginous clay which rests usually on talcose clays. The more common associated minerals are rutile, hematite, ilmenite, quartz, kyanite,

tourmaline, gold, garnet, zircon, etc. In the prairie washings the diamonds occur in a conglomerate consisting of quartz fragments covered with a thin bed of sand or earth. This deposit affords the finest stones. Other Brazilian localities are those of Bagagem, at which place a 247½ carat stone was found, and at Abaethe, Minas Geraes. In Bahia diamonds are found at Lencães; along the river Cacholira, especially at Surua and Sinorea; they occur also on the Salobro and other branches of the Pardo River.

By far the greatest portion of diamonds now obtained come from South Africa, their discovery dating from 1867. The diamond workings are of two kinds, river diggings and dry diggings. The river diggings are in the gravel of the Vaal River from Potchefstroom down to its junction with the Orange River, and along the latter as far as Hopetown, the principal workings being along the Vaal between Klip Drift and its junction with the Hart River. The dry diggings are chiefly in Griqualand-West, south of the Vaal River, on the border of the Orange Free State, about 640 miles northeast of Cape Town. There are here a number of limited areas approximately spherical or oval in form, with an average diameter of some 300 yards, the entire production area being all within a circle having a radius of about 2 miles. These mines were originally worked as individual claims, but they are now all consolidated in one gigantic monopoly, which practically controls the diamond output of the world. Some idea of the enormous output of the region may be gained from the statement that from 1867 to 1887 over 33,000,000 carats, or more than 6½ tons of diamonds were taken out, valued in the rough at \$225,000,000, and after cutting at \$450,000,000.

At the Kimberley mines the diamantiferous area is inclosed in a wall of nearly horizontal black carboniferous shale. The upper portion of the deposit consists of a friable mass of pale yellow color, called the "yellow ground." Below the reach of atmospheric influences the rock is more firm and of a bluish green color; it is called the "blue ground." This consists essentially of a serpentinous breccia inclosing fragments of carbonaceous shale, bronzite, diallage, garnet, magnetite, etc. The diamonds are rather abundantly distributed through the mass, often to the amount of four to six to the cubic yard. These areas are believed to be volcanic pipes, and the occurrence of the diamonds is obviously connected with the igneous intrusive, either being formed by the action of heat upon the carbonaceous shales, or being brought up from underlying rocks. (See pl. 14.)

For a detailed description of these occurrences the reader is referred to authoritative and comprehensive works like that of Mr. Gardner F. Williams (*The Diamond Mines of South Africa*), or M. DeLaunay (*Les Diamants du Cap*. Paris, 1897). Also reference should be

made to the very complete exhibit of rocks and minerals from the South African mines presented to the National Museum by Mr. Williams and described on page 134.

Diamonds were discovered in the Urals in 1829. They occur in the gold washings of the detritus along the Adolfskoi Creek, near Disersk, and elsewhere along the western declivity of the Uralian range. In Australia they are found in the alluvial of the Cudgegong River, near Mudgee; and in the valley of the Horton River, in the Bingera district of New South Wales.

A few crystals have been occasionally met with in the United States in Rutherford, Franklin, Mitchell, and McDowell counties, North Carolina; in Hall County, Georgia; in Kentucky, Ohio, Wisconsin, Colorado, and Idaho; and in the placers of Eldorado, Amador, Nevada, Butte, Trinity, and Del Norte counties, California. In 1856 the Dewey diamond, weighing when cut $11\frac{1}{2}$ carats, was found at Manchester, near Richmond, Virginia.

Diamond-bearing peridotites are at present being exploited in Pike County, Arkansas, and in microscopic forms have been reported from a peridotite in British Columbia. The commercial possibilities of these sources have not as yet been demonstrated.

LIST OF SPECIMENS.

INDIA.

102 small stones and 17 chips; brilliant; colorless; very clear; total weight 18.25 carats. Gift of the Imam of Muscat..... No. 1848

SOUTH AFRICA.

Five rough crystals, 3 white, one yellow, one brown; total weight, 1.52 carats. Gift of Gardner F. Williams..... No. 1000

UNION OF SOUTH AFRICA (KIMBERLEY, GRIQUALAND WEST).

Partly cut; colorless; 1.67 carats; 5 by 5 by 5..... No. 467
 Uncut; gray; 1.6 carats; octahedron, 5 by 5 mm. The Shepard collection. No. 1001
 Brilliant, rectangular girdle; colorless; 0.928 carat; 6 by 5 by 4 mm..... No. 466
 Brilliant, circular girdle; white; 0.25 carat; 4.5 by 3.5 mm. Isaac Lea collection..... No. 470
 Brilliant, circular girdle; yellow; 0.19 carat; 4 by 3.5 mm. Isaac Lea collection..... No. 471
 Brilliant, circular girdle; brown; 0.15 carat; 4 by 3 mm. Isaac Lea collection..... No. 472
 Brilliant, circular girdle; green; 0.14 carat; 3 by 3 mm. Isaac Lea collection..... No. 469
 Brilliant, circular girdle; pink; 0.13 carat; 4 by 3 mm. Isaac Lea collection..... No. 468

UNITED STATES.

Kentucky.

Cabin Fork Creek, near Montpelier, Adair County:

Uncut but polished; yellow; 0.776 carat; 8 by 4 by 3 mm. Isaac Lea collection..... No. 465

North Carolina.

Rutherford County:

Uncut; pale yellow; 0.14 carat; 3 mm. diameter; flattened octahedron.

The Shepard collection..... No. 1002

Diopside.—See under Pyroxene.**Emerald.**—See under Beryl.

EPIDOTE.

Composition.—Calcium aluminum iron orthosilicate, $\text{Ca}_2(\text{Al,Fe})_3(\text{OH})(\text{SiO}_4)_3$.*Crystallization.*—Monoclinic.*Color.*—Brown, green, green-yellow, or green-brown, owing to the presence of iron; strongly pleochroic, green to brown.*Luster.*—Vitreous.*Hardness.*—6.5; fairly durable.*Specific gravity.*— 3.30 ± 0.10 .*Optical properties.*—Mean refractive index 1.75; double refraction strong, 0.04; optically biaxial, negative.

With the microspectroscope epidote shows an absorption band in the violet. The color of the mineral is its most distinctive quality. It occurs in metamorphic rocks and in veins, and is little used as a precious stone owing to its intense color.

LIST OF SPECIMENS.

TYROL.

Step, rectangular girdle; dark brown; 3.92 carats; 14 by 8 by 3 mm..... No. 579

Step, rectangular girdle; dark green; 0.74 carat; 8 by 4.5 by 2 mm..... No. 580

Essonite.—See under Garnet.

EUCLASE.

Composition.—Beryllium aluminum orthosilicate, $\text{BeAl}(\text{OH})(\text{SiO}_4)$.*Crystallization.*—Monoclinic.*Color.*—Colorless when pure, but often colored pale green or blue by traces of iron.*Luster.*—Vitreous.*Hardness.*—7.5; very durable.*Specific gravity.*— 3.10 ± 0.05 .*Optical properties.*—Mean refractive index 1.66; double refraction moderate, 0.02; optically biaxial, positive.

The mineral can be distinguished only by its optical properties. Occurs in metamorphic rocks such as mica schist, but it is rare and not widely used as a gem.

LIST OF SPECIMENS.

BRAZIL.

Step-brilliant, square girdle; pale green; 1.06 carats; 7 by 4 mm..... No. 832

Fairy Stone.—See under Staurolite.

FELDSPAR.

Varieties.—This name includes several varieties, which are distinguishable by their crystallization and chemical composition, comprising albite, containing sodium (Na); labradorite, sodium and calcium (Na+Ca); microcline, potassium (K); oligoclase, sodium and calcium (Na+Ca); and orthoclase, potassium (K); and in addition several varieties based on peculiarities of structure or color, as amazonstone, adularia, moonstone, perthite, and sunstone.

Composition.—Silicates of potassium or sodium; in part, combinations of silicates of sodium with ortho-silicates of calcium, the element aluminum being present throughout. $KAlSi_3O_8$, $NaAlSi_3O_8$, and $mNaAlSi_3O_8 + nCaAl_2(SiO_4)_2$.

Crystallization.—Monoclinic or triclinic.

Color.—Colorless when pure; sometimes colored pink or green by impurities of unknown nature; in addition, may show internal reflection colors of two types, the one due to the presence of innumerable minute laminae, the other due to inclusions of hematite.

Luster.—Vitreous; transparent to translucent.

Hardness.—6; not very durable.

Specific gravity.—2.5 to 2.7.

Optical properties.—Mean refractive index, 1.53, varying from one kind of feldspar to another; optically biaxial.

The feldspars are distinguished by their optical properties, moderate hardness, pronounced cleavage, and peculiar color phenomena.

They are cut for the most part cabochon, to bring out color effects, and are classed as semiprecious stones. Only exceptionally fine stones are worth more than the cost of cutting. They are shown to best advantage in the varieties moonstone, orthoclase, and amazonstone.

UNITED STATES.

Pennsylvania.

Media, Delaware County:

Cabochon, elliptical girdle; two stones, one red-gray, one light gray; 56.37 and 19.67 carats; 43 by 32 by 6 mm. and 27 by 19 by 5.5 mm....	No. 1202
Tabular cabochon, rectangular girdle; gray with pale brown streaks; 6.77 carats; 19 by 11 by 3 mm. Gift of Dr. R. H. Lamborn.....	No. 1201

FLUORITE.

Synonym.—Fluor-spar.*Composition.*—Calcium difluoride, CaF_2 .*Crystallization.*—Isometric.

Color.—Colorless when pure, but usually showing disperse colors owing to the presence of submicroscopic particles of indeterminate nature; may be a beautiful yellow, green, blue, violet, or pink.

Luster.—Vitreous; transparent to translucent.

Hardness.—4; too soft for ordinary use as a precious stone, but can be used in ornaments, etc.

Specific gravity.— 3.18 ± 0.05 .

Optical properties.—Refractive index, 1.434; optically isotropic; may show fluorescence or different colors when viewed by reflected and transmitted light, but never pleochroism.

The mineral is distinguished by its softness, by its lack of double refraction, and its easy and perfect octahedral cleavage. It occurs in veins in many kinds of rocks, including the pegmatites.

It is used for paper weights, vases, and other ornaments, chiefly as curiosities, and is worth little more than the cost of cutting. Small faceted stones are sometimes cut from this mineral, but are not sold commercially.

LIST OF SPECIMENS.

UNITED STATES.

New Hampshire.

Chatham, Carroll County:

Brilliant, circular girdle; green-blue; 1.875 carats; 7.5 by 5 mm. Gift of
Sumner Andrews..... No. 358

Virginia.

Amelia Courthouse, Amelia County.

Step-brilliant, rectangular girdle; very pale smoky brown; 5.047 carats;
11 by 9 by 7 mm..... No. 357

GADOLINITE.

Composition.—Beryllium iron yttrium orthosilicate, $\text{Be}_2\text{FeY}_2\text{O}_2$
(SiO_4)₂.

Crystallization.—Monoclinic.

Color.—Black.

Luster.—Submetallic or brilliant vitreous; practically opaque except in very thin splinters.

Hardness.—6.5; fairly durable.

Specific gravity.— 4.40 ± 0.05 .

Optical properties.—Mean refractive index, 1.80; optically biaxial, positive.

Gadolinite can be distinguished from several minerals which it resembles only by chemical tests. It is sometimes cut brilliant, but its dark color prevents its extensive use as a precious stone, and it is worth little more than the cost of cutting.

Lea collection..... No. 587

GARNET.

There are three prominent groups of garnet with several subdivisions under each, many of these grading into each other. They are:

1. Aluminum garnet:

Grossularite.—Lime-aluminum garnet.

Pyrope.—Magnesium-aluminum garnet.

Almandite and rhodolite.—Iron-aluminum garnet.

Spessartite.—Manganese-aluminum garnet.

OPEN CUT EMERALD MINE, NOW ABANDONED, NEAR SHELBY, NORTH CAROLINA.

2. Iron garnet: Andradite.—Calcium-iron garnet.

3. Chromium garnet: Ouvarovite.—Calcium-chromium garnet.

The lime-aluminum garnet has a hardness of 7, a specific gravity of 3.55 to 3.66, and a considerable color range. The several varieties are: Essonite (cinnamon stone or hyacinth), of which the specimens of a clear yellow-brown to deep gold tinged with brown are more commonly used as gems. Grossularite includes the pale green, yellow to nearly white, pale pink, red-orange, and brown kinds. Romanzovite is a brown variety; wiluite is yellow-green to greenish white; topazolite is deep to pale yellow; and succinite is amber-colored.

The principal magnesian garnet is the pyrope, meaning "fire-like," a deep red to nearly black stone, prized as a gem. It is among the hardest of the garnets, ranking 7.5 in the scale. Its specific gravity lies between 3.7 and 3.8.

The almandite, or carbuncle, and rhodolite are iron-aluminum garnets. Almandite varies in color from bright red to deep red of several tints, occasionally assuming an orange hue by artificial light. The color of the rhodolite lies between a violet-purple and a brown-red. These varieties have a hardness of about 7.5, with a specific gravity seldom less than 4, and occasionally as high as 4.3. Both are prized as gems.

Spessartite is a manganese-aluminum garnet, varying in specific gravity from 3.7 to 4.3, and has a hardness of about 7. The color varies from a red-brown, sometimes with a tinge of violet, to orange red. It often affords fine gems.

The calcium-iron garnet varies in specific gravity between 3.6 and 4 and in hardness from 5 to 7. The group includes a diversity of forms, varying widely in color and other respects, the more important of which are: Andradite, a yellow or orange-brown variety; demantoid, or Uralian emerald, a grass-green, emerald-green, or brown-green stone having a brilliant luster, and when cut exhibiting considerable fire, especially by artificial light; colophonite, a brown-black garnet, characterized by a resinous luster; and melanite, a black to yellow-brown kind.

The calcium-chromium garnet, ouvarovite, is almost invariably a fine emerald green color, and is harder than any of the other varieties, ranking nearly 8 in the scale.

Garnet is common in mica, hornblende, and chlorite schist, gneiss and granite, occurring also in limestone, serpentine, and volcanic rocks (fig. 6). The garnet of granite, gneiss, mica schist, and similar rocks is commonly almandite. Grossularite is common in limestones and crystalline schists. Pyrope belongs especially to peridotites and the serpentines derived from them; occurs also in basalts. Spessartite occurs in granitic rocks, in quartzite, in certain schists, and in some rhyolites. Iron garnets are common in eruptive rocks, occurring also as a product of contact meta-

morphism. Demantoid occurs in serpentine. The chrome garnets belong particularly to serpentine; found also in granular limestone.

The mineral is widely used as a semiprecious stone, although the color is in some cases so deep that it is not much in favor. The most noted garnet region of the world is that some 60 kilometers north of Prague in Bohemia. For many years this has been almost the only commercial source of the common ruby garnet found mounted in various and multiple forms in the jewelers' shops.

Of late years a great many very beautiful garnets have been brought in from the Indian Reservations in Arizona and New Mexico, where they are gathered from the loose sands and gravels which result from

FIG. 6.—GARNETS IN MATRIX.

a decomposition of boulders of garnetiferous gneiss which, according to Gregory,¹ have been brought from an unknown depth to the surface by igneous injections. These are often of no mean quality and are popularly spoken of as Arizona rubies. The principal localities are the Mule Ear and Moses Rock fields in southern Utah and the Garnet Ridge field in the adjoining portion of Arizona.

GOLD.

Native gold, either in the form of leaf, nugget, or embedded in quartz, is often used in the form of scarf or breast pins and is hence recognized here by a characteristic form. It ranks, however, more as a curiosity or souvenir than as a commercial article.

LIST OF SPECIMENS.

Leaf gold mounted as a breastpin. California. Isaac Lea collection.....	No. 1779
---	----------

Graphic granite.—See under Miscellaneous on page 120.

Grossularite.—See under Garnet.

GYPSUM.

Synonyms or varieties.—Alabaster, satin spar, selenite.

Composition.—Hydrous calcium sulphate, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$.

Crystallization.—Monoclinic.

Color.—White or colorless.

Luster.—Vitreous or silky in fibrous varieties; transparent to translucent.

Hardness.—2; entirely too soft to be used as a precious stone.

Specific gravity.— 2.32 ± 0.05 .

Optical properties.—Mean refractive index, 1.525; double refraction weak, 0.009; optically biaxial, positive.

Method of identification.—Can be readily recognized by its softness. Gypsum occurs in great quantities interstratified with other sedimentary rocks, and the pure white varieties are worked under the name alabaster. Only the fibrous form, satin spar, is utilized as gem material and then only in small ornaments as statuettes, beads, etc. While the luster of the fibrous variety is attractive, its softness precludes its extensive use, and it brings little more than the cost of cutting.

LIST OF SPECIMENS.

GYPSUM, variety SATIN-SPAR.

ENGLAND.

- Cabochon, elliptical girdle; white; 32.03 carats; 29 by 18 by 12 mm. Gift of Clarence S. Bement..... No. 378
 Bridgeford:
 Two necklaces of 63 beads each, white, 8 mm. diameter..... No. 377

HEMATITE.

Composition.—Iron sesquioxide, Fe_2O_3 .

Crystallization.—Hexagonal (trigonal), rhombohedral.

Color.—Black; when finely powdered, red.

Luster.—Metallic; practically opaque.

Hardness.—6; fairly durable.

Specific gravity.— 5.20 ± 0.10 .

Optical properties.—Too opaque for determination of optical properties by ordinary means.

The mineral can be best distinguished from other black minerals by the color of its powder or its red "streak," made by rubbing it on unglazed porcelain. Occurs abundantly in beds and in veins and sedimentary rocks, but is too black for use as a precious stone. Is sometimes cut into beads, intaglios, etc., which have a value little more than cost of cutting.

LIST OF SPECIMENS.

ENGLAND.

- Two intaglios, tabular, rectangular; black; 17.29 and 17.23 carats; 18 by 15 by 3 mm..... No. 1245
 Intaglio, tabular, rectangular; black; 11.67 carats; 16 by 11 by 3 mm..... No. 1247
 Cumberland:
 Necklace of 48 beads, spherical; black; 12 to 8 mm. diameter..... No. 1246

Hiddenite.—See under Spodumene.

Huntelite.—See under Miscellaneous on page 120.

Hyacinth.—See under Zircon.

HYPERSTHENE.

Variety.—Bronzite.

Composition.—Magnesium and iron metasilicate, $(\text{Mg}, \text{Fe}) \text{SiO}_3$.

Crystallization.—Orthorhombic.

Color.—Black, with bronze internal color; pleochroism distinct under the microscope.

Luster.—Submetallic.

Hardness.—5.5; not very durable.

Specific gravity.— 3.50 ± 0.20 .

Optical properties.—Mean refractive index, 1.70; double refraction moderate, about 0.01; biaxial, negative.

Hypersthene and bronzite are members of the pyroxene family and are common constituents of certain types of volcanic rocks. They occasionally afford material that can be cut and are of interest but of little use as precious stones; are sometimes cut cabochon as a curiosity.

LIST OF SPECIMENS.

NORWAY (FREDRIKSVARN).

Cabochon, elliptical girdle; black with bronze luster; 15.67 carats; 22 by 16 by 5 mm..... No. 422

IOLITE.

Synonyms.—Cordierite, dichroite, "water-sapphire."

Composition.—Magnesium aluminum metasilicate, $\text{Mg}_4\text{Al}_8\text{O}_6(\text{SiO}_3)_{10}$.

Crystallization.—Orthorhombic.

Color.—Blue, usually somewhat smoky; strongly pleochroic, from yellow to blue.

Luster.—Vitreous; transparent.

Hardness.—7; a durable stone.

Specific gravity.— 2.65 ± 0.05 .

Optical properties.—Mean refractive index, 1.54; double refraction weak, 0.008; optically biaxial, negative.

The mineral occurs in pegmatite and in metamorphic rocks. When cut in such a direction that the blue color shows at the top, it is used to some extent as a precious stone. Its value is slight.

LIST OF SPECIMENS.

JADE.

Varieties.—Jadeite and nephrite.

Composition.—Jadeite, a mineral of the pyroxene group, is a sodium aluminum silicate ($\text{NaAl}(\text{SiO}_3)_2$) with a granular to fibrous but compact structure. Nephrite, a member of the amphibole group, is a magnesium calcium silicate ($\text{Mg}_3\text{CaSi}_4\text{O}_{12}$) with a fibrous structure.

Crystallization.—Monoclinic.

Color.—Gray or white when pure; often green, owing to the presence of small amounts of iron silicates; usually mottled because of irregular distribution of the coloring substance.

Luster.—Vitreous; translucent.

Hardness.—6.5; can not be scratched by a knife, and fairly durable.

Specific gravity.— 3.35 ± 0.10 .

Optical properties.—Mean refractive index for nephrite, 1.61; for jadeite 1.67.

Distinguished from imitations by its great hardness. True jade is not produced artificially, but green glass made cloudy by stirring in some pigment is sometimes used as an imitation. Not used as a precious stone in the ordinary sense, but, because of its hardness and toughness, has been much used, particularly by the Chinese, for ornaments, carvings, etc. The hardness renders work upon it difficult, and causes genuine jade articles to bring high prices. Ignorant buyers are often imposed upon by the substitution of a green serpentine for the real article. Jadeite can usually be distinguished from nephrite by its granular structure, nephrite being more distinctly fibrous.

LIST OF SPECIMENS.

JADE, variety JADEITE.

CHINA.

Carved buckle; bright green; 68 by 18 mm. Isaac Lea collection	No. 1813

Jadeite.—See under Jade.

Jasper.—See under Chalcedony.

KYANITE.

Synonym.—Often spelled cyanite.

Composition.—Aluminum oxy-orthosilicate, $Al_2O_3 (SiO_4)$.

Crystallization.—Triclinic; habit bladed.

Color.—Colorless when pure; often blue owing to the presence of impurities of unknown nature.

Luster.—Vitreous; translucent to transparent.

Hardness.—7 in one direction, 5 in the other; not very durable.

Specific gravity.— 3.60 ± 0.05 .

Optical properties.—Mean refractive index, 1.72; double refraction moderate, 0.015; optically biaxial, negative.

A great variation in hardness is highly characteristic. It is rarely found clear enough to be used as a precious stone, but is occasionally cut.

LIST OF SPECIMENS.

RUSSIA.

Step, rectangular girdle; blue; 0.579 carats; 7 by 4 by 2 mm..... No. 565

UNITED STATES.

North Carolina.

Spruce Pine, Mitchell County:

Step, rectangular girdle; deep blue; 3.728 carats; 12 by 7 by 5 mm.

Gift of D. A. Bowman..... No. 564

Kunzite.—See under Spodumene.

Labradorite.—See under Feldspar.

Lapis-lazuli.—See under Lazurite.

LAZURITE.

Synonym.—Lapis-lazuli.

Composition.—The ornamental stone known as lapis-lazuli is a mixture of a number of different minerals, but the principal one, yielding the blue color, is lazurite, a sodium aluminum sulpho-ortho-silicate, $\text{Na}_5\text{Al}_3\text{S}_3(\text{SiO}_4)_3$.

Crystallization.—Isometric.

Color.—Deep blue, due to the peculiar sulphur compound present.

Luster.—Vitreous; translucent.

Hardness.—5; rather too low for the stone to be durable.

Specific gravity.— 2.40 ± 0.10 .

Optical properties.—Refractive index, 1.49; isotropic.

The composite nature of the rock can easily be made out by close examination, specks of pyrite in particular being almost always visible. It is decomposed by hydrochloric acid with the evolution of hydrogen sulphide. It occurs in metamorphic rocks. The artificial blue pigment known as ultramarine is essentially identical with lazurite in composition. Blue glass and blue stained chalcedony are often put on the market as imitations. Lapis-lazuli is used in the manufacture of ornaments of various kinds, and, being rather difficult to carve, brings fairly high prices. It does not occur in masses of large size. The only mineral with which it is likely to become confounded is sodalite (see p. 97).

LIST OF SPECIMENS.

CENTRAL ASIA.

Watch charm carved in imitation of a grasshopper; deep violet-blue; 19.05 carats; 40 by 11 by 6 mm. No. 356

CHILE (ANDES MOUNTAINS).

Slab; oval; deep blue; 33.7 grams (168.6 carats); 65 by 35 by 7 mm. No. 355

PERSIA.

Leopardite.—See under Miscellaneous (Porphyry) on page 120.

Lintonite.—See under Thomsonite.

MALACHITE AND AZURITE.

Composition.—Hydrous copper carbonate, $\text{Cu}_2(\text{OH})_2(\text{CO}_3)$.

Crystallization.—Monoclinic.

Color.—Brilliant green, characteristic of many copper compounds.

Luster.—Vitreous, or, in fibrous varieties, silky; practically opaque.

Hardness.—3.5; can be used only where not subjected to wear.

Specific gravity.— 4 ± 0.05 .

Optical properties.—Mean refractive index, 1.88; double refraction extremely strong, 0.2; optically biaxial, negative.

The mineral dissolves with effervescence in hydrochloric acid, yielding a yellow solution which together with its color is sufficient in most cases for identification. Occurs like azurite in weathered copper ores, and is used for ornaments, especially table tops, etc., and was formerly valued very highly. As a rule, sound pieces of only moderate size are obtainable, and on the larger objects of art small pieces are very skillfully utilized as a thin veneer. Azurite is associated with malachite in the specimen figured below (fig. 7).

LIST OF SPECIMENS.
SIBERIA.

- Cabochon, circular girdle; banded green and brown; 70.8 carats; 34 by 6 mm. Isaac Lea collection (fig. 3, pl. 7). No. 1250
Tabular, elliptical girdle; banded dark and light green; 63.7 carats; 40 by 32 by 4 mm. No. 1248
Tabular, circular girdle; dark green with light-green concentric rings; 49.79 carats; 31 by 4 mm. No. 1249
Cabochon, elliptical girdle; dark and light green, banded; 42.67 carats; 33 by 26 by 5 mm. No. 1251

FIG. 7.—MALACHITE AND AZURITE.

Microcline.—See under Feldspar, variety Amazonstone.

MOLDAVITE: TEKTITE.

Synonyms and varietal names.—Local names dependent upon sources are common, as Australites, billitonites, and obsidian bombs. Suess proposes the general name *tektite* for the entire group.

Composition.—Glass high in silica, alumina, and the alkalis.

Crystallization.—None; amorphous.

Color.—Green to black.

Luster.—Vitreous.

Hardness.—6 to 7.

Specific gravity.—2.31 to 2.5.

Optical properties.—Refractive index variable, mostly low; optically isotropic.

Resembles in many cases ordinary green bottle glass. Its lower index of refraction distinguishes it from any natural crystalline mineral. Found loose on surface or in gravels in various parts of Australia, Bohemia, and Moravia, and thought by some to be of artificial, and by others of meteoric origin. The green variety, moldavite, has sometimes been cut as a gem stone, but is of value only as a curiosity.

LIST OF SPECIMENS.

MORAVIA.

Two stones, step-brilliant and brilliant, elliptical and rectangular girdles; dark green; 23.11 and 4.95 carats; 24 by 17 by 11 and 13 by 10 by 7 mm... No. 681

Moonstone.—See under Feldspar.

Moss Agate.—See under Chalcedony.

Nephrite.—See under Jade.

OBSIDIAN.

Synonyms or varieties.—Rhyolite glass, volcanic glass, hyaline rhyolite.

Composition.—Glassy volcanic rocks of variable composition, chiefly silicates of aluminum, iron, calcium, and the alkalis.

Crystallization.—None.

Color.—Various shades of black, brown, or red.

Luster.—Vitreous; transparent to translucent.

Hardness.—5.5.

Specific gravity.—Varying with composition, but mostly around 2.5.

Optical properties.—Refractive index variable, but mostly about 1.6; optically isotropic.

The resemblance to ordinary glass usually distinguishes this material from other stones, but its isotropic character and low index of refraction are usually confirmatory tests. Obsidian is of common occurrence in many volcanic regions, where it is a result of the rapid cooling of a molten magma that under different conditions might have become crystalline. Artificial glasses similar in appearance to obsidian can readily be prepared. The variegated and more brilliantly colored varieties have sometimes been cut, but the color is rarely sufficiently attractive to give it any value other than as a curiosity.

LIST OF SPECIMENS.

MEXICO (AZTEC OBSIDIAN MINE, NEAR REAL DEL MONTE, HIDALGO).

Two elliptical disks; black; 21 by 17 by 3 mm. No. 685

Oligoclase.—See under Feldspar.

Olivine.—See under Chrysolite.

Onyx.—See under Chalcedony.

OPAL.

Composition.—Silica, containing a variable amount of water ($\text{SiO}_2 + n\text{H}_2\text{O}$).

Crystallization.—None; amorphous.

Color.—Colorless when pure, but often tinted pink, blue, and even black by impurities; shows a very brilliant internal reflection color owing to the presence of innumerable minute laminae.

Luster.—Vitreous; transparent to translucent.

Hardness.—6; by reason of this moderate degree of hardness, its brittleness, and its porous nature, is not very durable under ordinary conditions of wear.

Specific gravity.— 2.1 ± 0.1 .

Optical properties.—Refractive index somewhat variable because of differences in water content, but chiefly about 1.40; optically isotropic except where irregular distribution of the water content causes strain phenomena, when double refraction may be observed.

No other precious stone approaches opal in the internal color, so that this property, together with the low specific gravity and index of refraction, serves to identify it.

There are many varieties to which specific names have been given. The precious opal exhibits a play of delicate colors, reflecting now one hue and then another. The harlequin opal presents a variegated play of colors on a reddish ground and resembles the fire opal. The fire opal presents red to yellow colors, with firelike reflections, somewhat irised on turning. Girasol is a blue-white translucent kind, presenting red reflections in a strong light. Lechosos opal is a name applied to those kinds showing deep green flashes of color. Hydrophane is a white or light colored opaque kind which becomes transparent when immersed in water. Cacholong is opaque porcelain-white, blue-white, pale yellow, or red. Opal agate is agatelike in structure. Jasp-opal contains several per cent of iron, and is the analogue in opal of jasper in quartz. Wood opal is wood silicified by opal; sometimes called lithoxyle when showing a woody structure. Hyalite, or Muller's glass, is either colorless and pellucid like glass, or a translucent blue-white. Moss opal contains mosslike inclusions of manganese oxide and is the analogue in opal of the moss agate in

quartz. Tabasheer is an amorphous, opal-like silica deposited within the joints of bamboo; it absorbs water and becomes transparent like hydrophane.

Opal occurs as a secondary deposit in fissures in many kinds of rocks, also in petrified wood and other fossil material, being deposited in the gelatinous form from solutions of silica, and hardening as water is gradually expelled. Material of the composition of opal can be readily produced artificially, but it has never proved possible to reproduce the brilliant internal color phenomena shown by the natural mineral. Opal is always cut cabochon to bring out the color to the best advantage, and, while not always of great value, it becomes at times one of the most beautiful and fascinating of gems and is correspondingly expensive.

The chief commercial sources are Australia, Hungary, and Mexico. Recently deposits in Nevada (pl. 9), have become important sources, producing black opals of extraordinary size and beauty.

PEARL.

Calcium carbonate is most widely distributed in a number of forms, the varieties depending upon differences in origin, crystallization and structural condition, presence of impurities, etc. With the exception of pearl and coral, the many forms are used more for decorative purposes than for personal adornment.

Pearls are concretions, or, more correctly, secretions, consisting essentially of calcium carbonate, found in the shells of certain mollusks. They are the result of an abnormal secretory process caused by an irritation of the mantle of the mollusk, resulting from

FIG. 8.—BAROQUE PEARLS.

the introduction into the shell of some foreign body, such as a grain of sand.

Pearls possess a luster peculiar to themselves, which is called pearly or nacreous. This luster may exist on the exterior surface only of the concretion, or the outer surface may be dull and dead in luster while an inner surface may be clear and lustrous. Their specific gravity is 2.5 to 2.7; their hardness 2.5 to 3.5. They may be of any shape, and in some instances of considerable size. In color they range from an opaque white, through pink, yellow, purple, red, green, brown, blue, black, in all shades; in addition they may be iridescent. In general, their color and luster will be that of the interior shell surface adjacent to which they are formed.

The beauty and value of pearls is dependent upon their color, texture or "skin," transparency or "water," luster, and form, the

most valuable being those which are round or pear-shaped, slightly transparent, free from specks or blemishes, and possessing to the highest degree the characteristic luster.

Pearls are liable to deteriorate with age, contact with acids, gases, and vapors, and though various methods are in use for restoring them to their original beauty, they are by no means to be relied upon, so that care should be taken to preserve fine pearls by wiping them after use with a clean, soft cloth and keeping them wrapped and in a closed box.

Although nearly all bivalves with nacreous shells occasionally yield pearls, practically all of those of commerce are obtained from only a few families of mollusks, prominent among which are the Aviculidae, Unionidae, and Mytilidae. The pearl oyster of the Pacific and Indian oceans, which has yielded the bulk of the pearls of the world, belongs to the first of these groups. The unio, or fresh-water mussel, so abundant in the rivers and lakes of North America, belongs to the second.

The name baroque is given to irregular and sometimes almost grotesquely contorted forms, formerly considered of little value, but now when of good color highly prized. A series of these from fresh-water streams in the Mississippi Valley is shown in figure 8.

Peridot.—See under Chrysolite.

Perthite.—See under Feldspar.

PHENACITE.

Composition.—Beryllium ortho-silicate, Be_2SiO_4 .

Crystallization.—Hexagonal (trigonal), rhombohedral.

Color.—Colorless when pure; sometimes colored yellow by traces of impurities.

Luster.—Vitreous; transparent.

Hardness.—7.5; very durable.

Specific gravity.— 2.95 ± 0.02 .

Optical properties.—Mean refractive index, 1.66; double refraction moderate, 0.02; optically uniaxial, positive.

The mineral is best identified by its optical properties. It occurs in pegmatites and in veins, and is a rare mineral and not widely used as a precious stone, although it approaches the diamond in brilliance, especially in artificial light. The name, from *φίναξ*, deceiver, is said to have been applied on this account.

LIST OF SPECIMENS.

SIBERIA.

- Brilliant, rectangular girdle; colorless; 5.22 carats; 12.5 by 11 by 7 mm.
 Isaac Lea collection No. 830
 Brilliant, square girdle; colorless; 2.14 carats; 8 by 5 mm..... No. 831

Plasma.—See under Chalcedony.

Porphyry.—See under Miscellaneous on page 120.

Prase.—See under Chalcedony.

PREHNITE.

Variety.—Chlorastrolite.

Composition.—Hydrogen calcium aluminum ortho-silicate,
 $H_2Ca_2Al_2(SiO_4)_3$.

Crystallization.—Orthorhombic.

Color.—White when pure, but usually pale green, probably owing to the presence of iron. The variety chlorastrolite is mottled green and white.

Luster.—Vitreous; in chlorastrolite somewhat silky; translucent.

Hardness.—6.5; too hard to be scratched readily by a knife; fairly durable.

Specific gravity.— 2.90 ± 0.10 .

Optical properties.—Mean refractive index, 1.63; double refraction strong, 0.03; optically biaxial, positive.

The mineral is distinguished by its hardness and optical properties from other minerals that resemble it. It is found in veins and cavities in basic igneous rocks, especially basalt and diabase.

Ordinary prehnite is rarely cut as a precious stone, as its color is too pale to be attractive. The variety chlorastrolite, which is mostly obtained from the beaches of Lake Superior, is cut cabochon to bring out the fibrous structure, and is used in scarfpins, etc. It brings but a moderate price, only enough to pay for handling.

New Jersey.

Hoxie's Quarry, Paterson, Passaic County:

Cabochon, rectangular girdle; light green; 49.8 carats; 54 by 14 by 8 mm	No. 361
Two gems, cabochon, circular girdle; light green; 11.98 and 11 carats; 17 by 6 and 17 by 5 mm.	No. 362

PREHNITE, variety CHLORASTROLITE.

Michigan.

Isle Royal, Lake Superior:

Cabochon, elliptical girdle; dark and light green, mottled; 12 carats; 20 by 17 by 4 mm. (fig. 2, pl. 7)	No. 364
Cabochon, elliptical girdle; dark and light green, mottled; 5.43 carats; 12 by 8.5 by 6 mm	No. 363
Four polished stones, irregular; dark and light green, mottled; largest, 7.7 carats; total weight of three small stones, 3.29 carats; largest 16 by 11 by 7 mm.	No. 366
Three polished stones, two cabochon, one double cabochon; gray-green with dark green spots; 6.035, 4.87, and 3.67 carats; 17.5 by 12 by 3, 14 by 11 by 4, and 13 by 8 by 4.5 mm. Isaac Lea collection.	No. 365

PYRITE.

Synonym.—Sulphur-diamond.

Composition.—Iron disulphide, FeS_2 .

Crystallization.—Isometric.

Color.—Brass yellow.

Luster.—Metallic, opaque.

Hardness.—6; can not be cut by a knife; fairly durable.

Specific gravity.— 5 ± 0.05 .

Optical properties.—Indeterminate.

Miscellaneous properties.—Some varieties are easily decomposed by moist air, losing their luster and gradually falling to pieces. The color and luster are characteristic.

Pyrite is a very unstable mineral but occurs in a great variety of geological situations. It is used usually without cutting or polishing, as the natural luster is very brilliant. Being a very common mineral it is sold for little more than the cost of trimming and mounting.

LIST OF SPECIMENS.

UNITED STATES.

Pennsylvania.

Schuylkill County:

Two pieces, one oval, one rectangular girdle; brass yellow; 20 by 14 by 7 and 13 by 10 by 7 mm. Gift of J. W. Beath No. 678

Pyrope.— See under Garnet.

PYROXENE, variety DIOPSIDE.

Composition.—Calcium magnesium meta-silicate, $\text{CaMg}(\text{SiO}_3)_2$.

Crystallization.—Monoclinic.

Color.—Pale green, owing to the presence of a small amount of ferrous iron.

Luster.—Vitreous.

Hardness.—6; not very durable.

Specific gravity.— 3.25 ± 0.1 .

Optical properties.—Mean refractive index, 1.71; double refraction strong, 0.03; optically biaxial, positive.

The mineral occurs in metamorphosed limestones. The color, as a rule, is not attractive enough to make it of much importance as a precious stone.

FIG. 9.—LARGE AMETHYSTINE QUARTZ.

QUARTZ.

Varieties.—Silica, silicon dioxide, occurs in nature under a great variety of forms, which are usually divided into (1) phenocrystalline or vitreous varieties, (2) the cryptocrystalline varieties, and (3) the amorphous or colloidal varieties. Here are included the glassy, sometimes well crystallized forms, known under the names of quartz, rock crystal, amethyst, citrine, and smoky quartz; the massive forms occurring mainly in veins, known as rose, or milky quartz, according to color; and a few others with local or trade names. Under the cryptocrystalline and amorphous varieties are included those which have, to the naked eye, no evidence of having any crystalline

structure, but which are so dense as to appear almost amorphous. (See under Chalcedony and Opal.)

Composition.—Essentially silicon dioxide, SiO_2 ; some varieties contain admixed iron oxides.

Crystallization.—Hexagonal (trigonal), trapezohedral; crystal habit usually prismatic, with pyramidal terminations (fig. 9); some varieties, such as chalcedony, are only known in the cryptocrystalline condition.

Color.—Colorless when pure, but many of its important varieties are based on colors due to the presence of impurities.

Luster.—Vitreous; in some varieties, waxy; transparent to opaque.

Hardness.—7; very durable.

Specific gravity.—2.66 when pure, but varying considerably in impure forms.

Crystallized quartz has a mean refractive index of 1.55 and is optically uniaxial and positive. The chief means of its ready determination are, however, its hardness, which is such that it will scratch glass, its lack of cleavage, and general glasslike appearance and fracture. It is one of the most common of minerals. Small crystals have been produced by artificial means, but never in sizes or colors to rival the natural material. Quartz and the cryptocrystalline varieties of silica are much used in the cheaper grades of jewelry, and it can be scarcely regarded as more than a semiprecious stone, although the better grades of amethyst are very beautiful. The other varieties are worth little more than the cost of cutting. (See further under Chalcedony.)

The chief commercial source of amethyst used in jewelry is the Department of Artigas in northwestern Uruguay and adjacent parts of Brazil. A great deal of the material is exported to Germany, cut, and distributed throughout the world. Cut stones of the material are to be found in all of the leading towns of the United States, and are often sold to the unwary public as a local product. The large botryoidal mass of crystals shown in a special case at the end of the mineral hall is stated to have come from a gigantic geode found in 1900 in the Province of Rio Grande do Sul, Brazil.

Rhodolite. See under Garnet.

RHODONITE.

Composition.—Manganese metasilicate, $MnSiO_3$.

Crystallization.—Triclinic.

Color.—Pink, characteristic of manganese compounds.

Luster.—Vitreous; translucent.

Hardness.—6; not very durable.

Specific gravity.— 3.50 ± 0.10 .

Optical properties.—Mean refractive index, 1.73; double refraction moderate, 0.01; optically biaxial, negative.

Alters to black manganese oxides in moist air. The mineral is distinguished by its color, rather high specific gravity, and optical properties. It is sometimes cut cabochon and used for scarfpins, buttons, etc., but more often carved into ornaments. Worth little more than the cost of cutting.

LIST OF SPECIMENS.

Rock crystal.—See under Quartz.

Ruby.—See under Corundum.

RUTILE.

Variety.—Nigrine.

Composition.—Titanium dioxide, TiO_2 ; may also contain small amounts of iron, vanadium, chromium, and other metal oxides.

Crystallization.—Tetragonal; habit usually prismatic, and at times acicular (needlelike).

Color.—Usually red, varying to black in the variety nigrine, these colors being largely due to the impurities, especially vanadium oxide; pleochroism distinct.

Luster.—Adamantine to submetallic; transparent to opaque.

Hardness.—6.5; fairly durable.

Specific gravity.— 4.20 ± 0.10 .

Optical properties.—Mean refractive index 2.75; double refraction extremely high, 0.3; optically uniaxial, positive.

The mineral may as a rule be identified by the high specific gravity, refractive index, and double refraction. Occurs in metamorphic rocks of various kinds and often in acicular crystals penetrating quartz, giving rise to the forms known as sagenitic quartz, Venus's hair stone, fleche d'amour, etc. Rutile is sometimes cut faceted, but the color is too dark and not very attractive, hence it is not widely used as a precious stone. Sagenitic quartz often yields ornamental stones. Rutile is worth little more than the cost of cutting.

LIST OF SPECIMENS.

UNITED STATES.

North Carolina.

Hiddenite, Alexander County:

Five gems, brilliant, circular girdle; dark red, nearly opaque; total weight, 2.93 carats; average size, 5 by 3 mm No. 457

SAMARSKITE.

Composition.—Complex iron, yttrium, and uranium columbate.

Crystallization.—Orthorhombic.

Color.—Black.

Luster.—Submetallic; practically opaque.

Hardness.—5.5; not durable.

Specific gravity.— 5.70 ± 0.50 .

Optical properties.—Indeterminate.

Methods of identification.—Can be recognized more or less definitely by the luster and specific gravity, but can be distinguished from closely related minerals only by analysis.

Occurrence.—Occurs in pegmatite rocks and is sometimes cut brilliant, and is used in place of jet, but is of no greater value than cost of cutting.

LIST OF SPECIMENS.

UNITED STATES.

North Carolina.

Mitchell County:

Brilliant, circular girdle; black, opaque; 6.55 carats; 12 by 6 mm. Isaac

Lea collection No. 588

Sapphire.—See under Corundum.

Sardonyx.—See under Chalcedony.

Satelite.—See under Serpentine.

Satin spar.—See under Gypsum.

Selenite.—See under Gypsum.

SERPENTINE.

Varieties.—Williamsite, satelite, precious serpentine, verde-antique.

Composition.—Hydrous magnesium silicate, $H_2Mg_3Si_2O_9$.

Crystallization.—Probably monoclinic, but never found in good crystals.

Color.—Normally green, owing to a small amount of ferrous iron replacing the magnesium.

Luster.—Vitreous or somewhat greasy; translucent.

Hardness.—4; does not wear well.

Specific gravity.— 2.5 ± 0.2 .

Optical properties.—Mean refractive index 1.53; double refraction very weak.

The mineral may be distinguished by its softness, color, and by chemical tests. It occurs as a secondary product in rocks of many kinds, both igneous and metamorphic. It is used mainly as an ornamental stone and is too soft to be of great value as a gem. The variety williamsite is sometimes cut cabochon and used in scarf pins, as are also the fibrous forms. A beautiful variety from the Yu-Yen district of South Manchuria, China, is often carved into various forms and sold to the unwary for jade. According to Dr. J. Morgan Clements it is known locally as Yu Yen Shi (Stone of Yu Yen), or Yu Yen Yue (Jade of Yu Yen).

of Dr. Robert H. Lamborn..... No. 372

Silicified Wood.—See under Chalcedony.

SMITHSONITE.

Composition.—Zinc carbonate, $ZnCO_3$.

Crystallization.—Hexagonal (trigonal), rhombohedral.

Color.—White when pure, but often yellow, green, or blue, owing to the presence of impurities, especially copper carbonates.

Luster.—Vitreous; translucent.

Hardness.—5; not durable.

Specific gravity.— 4.40 ± 0.05 .

Optical properties.—Mean refractive index, 1.7; double refraction very strong, 0.2; optically uniaxial, negative.

The mineral dissolves with effervescence in hydrochloric acid, as does calcite and several other carbonates, from which it can be distinguished only by reacting for zinc. It is found as a secondary product associated with sulphide zinc ores above the permanent water level. Bright colored specimens are sometimes cut cabochon and used for scarfpins, etc. The value, however, is little greater than the cost of cutting.

Crystallization.—Isometric.

Color.—Intense blue.

Luster.—Vitreous; translucent.

Hardness.—5.5; not durable.

Specific gravity.— 2.20 ± 0.05 .

Optical properties.—Refractive index, 1.48; optically isotropic.

The mineral may be distinguished from lazurite, the mineral with which it is most likely to be confounded, by failure to evolve hydrogen sulphide when treated with acids. It is occasionally cut cabochon, but not widely used and of no great value. By artificial light nearly black in color.

LIST OF SPECIMENS.

UNITED STATES.

Maine.

Litchfield, Kennebec County:

Cabochon, elliptical girdle; deep blue; 4.44 carats; 14 by 12 by 5 mm. . . No. 367

Spessartite.—See under Garnet.

SPHALERITE.

Synonym.—Zinc-blende.

Composition.—Zinc sulphide, ZnS , with some iron replacing zinc, to which the color is probably due.

Crystallization.—Isometric; tetrahedral; showing prominent dodecahedral cleavage.

Color.—Colorless when pure, but usually pale yellow or brown because of the presence of traces of iron and possibly other elements.

Luster.—Adamantine to resinous; transparent to translucent.

Hardness.—4; too soft to be of much use as a precious stone.

Specific gravity.— 4 ± 0.10 .

Optical properties.—Refractive index, 2.37. Isotropic.

The mineral dissolves in hot hydrochloric acid with evolution of hydrogen sulphide. This and its optical properties will usually suffice for its determination. It occurs in veins, beds, and pockets, and is used chiefly as an ore of zinc. Clear material suitable for cutting as a precious stone is exceptional and its use limited.

Step-brilliant, square girdle; deep yellow; 12.45 carats; 12 by 9 mm. No. 589
Step-rose, circular girdle; yellow; 6.02 carats; 11 by 6.5 mm No. 590

SPINEL.

Varieties.—Balas ruby or spinel ruby.

Composition.—Magnesium aluminate, $MgAl_2O_4$, with some iron or other elements replacing magnesium and aluminum.

Crystallization.—Isometric.

Color.—Usually red, owing to the presence of small amounts of chromium; also colored green by iron or blue by cobalt.

Luster.—Vitreous; transparent.

Hardness.—8; an extremely durable stone.

Specific gravity.— 3.7 ± 0.2 .

Optical properties.—Refractive index, 1.72; in ordinary varieties, optically isotropic.

With the microspectroscope red and green varieties show no well-defined absorption bands, but blue varieties show a strong band in the green and one in the blue, characteristic of the metal cobalt. The mineral may be distinguished from true ruby and sapphire by the isotropic character, and from other stones by the properties above listed.

Following the order of the prismatic hues there are red, orange, yellow, green, blue, indigo, and violet colored spinels; and also there are those showing a whole series of intermediate hues, such as pink, heliotrope, lavender, lilac, purple, fawn, corn color, etc. The transparent, lively, red-colored spinel is called *spinel ruby*, and may readily be taken for the true ruby, though its small refractive and dispersive power, together with the absence of pleochroism, render it less brilliant than and lacking the fire of the red corundums. The

rose-red to pink-colored kinds are called *balas ruby*; the yellow or orange-red spinels are known as *rubicelle*; the violet and purple ones as *almandine*; the pale to sapphire-blue kinds as *sapphirine*; the blacks as *pleonast*.

Spinel occurs embedded in granular limestone, and with calcite in serpentine, gneiss, and allied rocks; occurring also in cavities in the ejected masses from certain volcanoes. Found also as rolled pebbles in certain alluvials, such as those of Ceylon and Burma, where it occurs in water-worn masses of fine colors in the channels of streams, along with quartz, garnet, tourmaline, sapphire, zircon, and other gem minerals. Spinel ruby is frequently found along with the ruby corundum in the crystalline limestone of the ruby mines of Burma. Most of the gem spinel comes from Ceylon, Burma, Siam, India, and other eastern countries. Small crystals of good color are found in the gem-bearing gravel of Expailly, France. The old lavas of Monte Somma, Italy, afford small black crystals of great brilliancy. A pale blue to pearl gray kind is found in the limestone near Aker, Sweden. From Amity, New York, to Andover, New Jersey, a distance of about 30 miles, is a region of granular limestone and serpentine in which localities of spinel abound, the crystals sometimes being fine enough to afford green, black, brown, and, less commonly, red gems. The localities near Franklin, New Jersey, yield crystals of various shades of black, blue, green, and red, which will occasionally afford small gems. While in some demand as a precious stone it is not as generally sought as the ruby varieties of corundum.

SPODUMENE.

Varieties.—Hiddenite and kunzite.

Composition.—Lithium aluminum metasilicate, $\text{Li, Al}(\text{SiO}_3)_2$. The variety hiddenite carries a little chromium, to which it is thought its color may be due.

Crystallization.—Monoclinic; prismatic.

Color.—White to yellow, rarely amethystine. Hiddenite, yellow green to emerald green; kunzite, pale pink.

Luster.—Vitreous, transparent to translucent.

Hardness.—6.5 to 7.

Specific gravity.—3.13 to 3.20.

Optical properties.—Refractive index, 1.66; pleochroism strong.

Hiddenite, or lithia emerald, is a variety of spodumene varying in color from a yellow-green to a deep emerald-green tinged with yellow, the colors of the crystal usually being yellow at one extremity and a more or less deep green at the other. The deeper colored kinds afford a gem resembling the emerald, but having a greater variety of color because of its strong pleochroism. The mineral occurs in slender prismatic crystals one-half inch to 2 inches in length, affording small gems only, the largest being under 3 carats in weight. Hiddenite is at present known from but one locality, Stony Point, Alexander County, North Carolina, where it is found in metamorphic

rocks, generally gneiss or mica schist, in veins of kaolin. The associated minerals are quartz, mica, rutile, beryl, and feldspar.

Kunzite is a pale pink to amethystine variety discovered within the past few years in the pegmatite dikes near Pala, San Diego County, California. It affords very handsome, delicately tinted stones. (See pegmatite collection in the geological hall.)

Most of the gem spodumene other than that mentioned above comes from the province of Minas Geraes, Brazil, where it occurs rather abundantly in crystals closely resembling chrysoberyl in color.

STAUROLITE.

Synonyms.—Cross-stone, fairy-stone.

Composition.—Iron aluminum hydroxy silicate, $\text{FeAl}_3(\text{OH})(\text{SiO}_6)_2$.

Crystallization.—Orthorhombic, habit prismatic; frequently twinned in cross or star-like forms.

Color.—Brown, due to the iron present; slightly pleochroic.

Luster.—Vitreous; translucent to opaque.

Hardness.—7 when unaltered, but sometimes less because of decomposition.

Specific gravity.— 3.70 ± 0.05 .

Optical properties.—Mean refractive index, 1.75; double refraction weak, 0.01; optically biaxial, positive.

The mineral occurs in metamorphic rocks, especially mica schist and is usually recognized from the cruciform character of its crystals. This peculiar cross or star shape of the crystal renders well-developed specimens somewhat prized for ornaments. The crystal faces are usually coated with mica when found, but this can be readily scraped off with a knife and the surfaces can be improved by polishing slightly, and the mineral is usually put on the market in this form. The natural crystals are often ground on the edges to "improve" the cross-like effect. The values are purely nominal.

FIG. 11.—STAUROLITES OR "FAIRY STONES."

LIST OF SPECIMENS.

LOCALITY NOT RECORDED.

Five crosses of various sizes. Gift of H. P. Petersen (fig. 11) No. 1029
Sunstone.—See under Feldspar.

THOMSONITE.

Variety.—Lintonite.

Composition.—Aluminum, calcium, and sodium hydrous silicate.

Crystallization.—Orthorhombic, commonly columnar radiated.

Color.—Variable flesh-red, yellow, green, and white.

Luster.—Vitreous, inclined to pearly.

Hardness.—5.5.

Specific gravity.—2.4.

Optical properties.—Doubly refracting, mean refractive index 1.503.

The mineral occurs as a secondary product in radiating and concretionary forms, filling amygdaloidal cavities in basic lavas. On exposure these lavas sometimes break down and the amygdules are liberated, and in the Lake Superior region often accumulate as pebbles in considerable quantities along the beaches, whence they are gathered to be cut for local souvenirs. The value is little more than cost of cutting.

- Four stones, cabochon, elliptical girdle; mottled various colors; 5.97, 5.95, 5.76, and 4.49 carats; 14 by 11 by 6, 15 by 11.5 by 5, 13 by 11 by 7, and 18 by 8 by 5 mm. Isaac Lea collection..... No. 1261

Thulite.—See under Zoisite.

Tiger Eye.—See under Crocidolite.

TITANITE.

Synonym.—Sphene.

Composition.—Calcium titanium oxy-orthosilicate, $\text{Ca}(\text{TiO})(\text{SiO}_4)$.

Crystallization.—Monoclinic; usually wedge shaped.

Color.—Gray when pure, but usually colored yellow, green, or brown by iron, manganese, or other metals not as yet recognized.

Luster.—Adamantine; transparent.

Hardness.—5.5; not very durable.

Specific gravity.— 3.50 ± 0.05 .

Optical properties.—Mean refractive index, 1.95; double refraction very strong, 0.15; optically biaxial, positive. Slightly pleochroic.

The high index of refraction renders titanite very brilliant, the play of colors, in fact, approaching that of the diamond. It is best distinguished by the optical properties.

Titanite occurs in metamorphic rocks, both limestone and schist, as well as in veins, from which the best quality stones are obtained. It is usually cut faceted; the inferior hardness renders it somewhat unsatisfactory as a precious stone.

TOPAZ.

Composition.—Aluminum fluo-orthosilicate, $\text{Al}_2(\text{F},\text{OH})_2(\text{SiO}_4)$.

Crystallization.—Orthorhombic; habit prismatic; cleavage basal.

Color.—Colorless when pure, but often showing disperse colors due to constituents of unknown nature; may be pale blue, pale yellow, or pink; pleochroism weak.

Luster.—Vitreous; transparent.

Hardness.—8; a very durable stone.

Specific gravity.— 3.50 ± 0.05 .

Optical properties.—Mean refractive index, 1.62; double refraction weak, 0.008; optically biaxial, positive.

The best colorless topazes have considerable fire, and, when properly cut, exhibit brilliant reflections of white light, approximating that of the diamond. The pink topaz is probably not known in

FIG. 12.—TOPAZ CRYSTAL IN MATRIX.

nature, the delicate tint being commonly obtained by heating the yellow or brown colored stones. The process of "pinking" is quite simple. The selected stone is packed in magnesia, asbestos, or lime, and carefully heated to a low red heat, care being taken that the temperature is raised gradually; the stone is then allowed to cool slowly. If the temperature reached has been sufficiently high, the desired pink tint is obtained; if not high enough, a salmon tint; if too high or too long continued, the color is lost completely.

There are several distinct minerals which are commonly called topaz—the topaz proper; the yellow sapphire known as the "oriental topaz;" and certain colored quartzes, known as "Saxon," "Scotch,"

“Spanish,” “smoky,” and “false topaz.” These stones vary rather widely in hardness and specific gravity, which, together with the power of developing frictional electricity possessed by the true topaz, furnishes a ready means for their discrimination. Thus:

Name.	Hardness.	Specific gravity.
Oriental topaz.....	9	4.01
True topaz.....	8	3.53
Scotch topaz, etc.....	7	2.65

Topaz occurs in gneiss or granite, associated with tourmaline, mica, beryl, etc., and occasionally with apatite, fluorite, and cassiterite; occurs also in certain talcose rocks, in mica slate, in rhyolite, and in alluvial deposits and drift (fig. 12). It is cut faceted and the better grades are highly valued as a precious stone.

TOURMALINE.

Varieties.—Achoroite, colorless; indicolite, blue; rubellite, pink.

Composition.—A complicated boro-silicate of magnesium, iron, aluminum, and alkali metals.

Crystallization.—Hexagonal (trigonal), hemimorphic; habit usually prismatic with strong vertical striation and different terminal faces at the opposite ends of the crystal.

Color.—Colorless when containing but traces of iron, but usually colored intensely blue, green, brown, pink, to dense black, etc., by iron, manganese, chromium, or possibly other elements; strongly pleochroic.

Luster.—Vitreous; transparent to translucent and opaque.

Hardness.—7; a durable stone.

Specific gravity.—Varying considerably with composition, but averaging 3.1.

Optical properties.—Mean refractive index varying with the composition, but usually about 1.65; double refraction moderately strong, 0.02; optically uniaxial, negative.

The matter of color is of interest. Some specimens are of one color only; others are green at one extremity and red at the other; some are green, then yellow, red, and finally green; others are crimson, tipped with black, or dark green passing into blue. A crystal may be white at the termination, then green of varying shades, pink and colorless, and in cross section dark blue or red at the center, surrounded by concentric layers of white, pink, and green. Another specimen may be red internally, passing into a lighter hue and finally green, or it may be blue or black internally, then red, and then green externally. In some specimens the different colors pass imperceptibly into one another; in others the line of demarcation is well defined.

The optical structure of the tourmaline is unique. When a crystal is viewed along the direction of its vertical axis it is less transparent and of different color than when viewed across that axis. For instance, a crystal viewed through the side is a transparent green, but when viewed through the end of the prism it may be either opaque or yellow green.

The marked pleochroism of the colored tourmalines influences to a great degree the appearance of the fashioned stone. For example, if a green-colored specimen is cut so that the table is parallel with the vertical axis of the crystal, the gem will exhibit a play and interchange of colors of two shades of green; if, however, the specimen is so cut that the table of the fashioned stone is perpendicular to the vertical axis, the gem will appear more or less opaque and dark colored, and will exhibit its transparency and green coloring only when viewed across the girdle. Care should be taken, therefore, in fashioning the tourmaline that the table is parallel with the vertical axis of the crystal; further, the facets of the crown should be large and well developed in order to exhibit to the utmost the differences of color for light transmitted in different directions as the gem is viewed from different positions.

The geological occurrence of the four types of tourmaline is of interest. The lithia group—which is often beautifully colored and affords the best gem material—is associated with soda and potash feldspar in pegmatite veins along with lepidolite and muscovite. The iron and the magnesia-iron groups, which are commonly black or brownish black, occur in granites, gneisses, schists, and also to a certain extent in pegmatites along with the lithia group. The magnesia group—commonly brown in color—occurs chiefly in crystalline magnesian limestones associated with mica, pyroxene, scapolite, etc.

In the United States magnificent colored tourmalines have been found in Maine at Auburn, Hebron, Norway, Andover, Rumford, Standish, and Paris. (See pl. 10.) The famous locality at Mount Mica, near Paris, was discovered in 1820, and for many years yielded fine specimens of green and parti-colored tourmalines. Some crystals

were over an inch in diameter, transparent ruby red within, surrounded by green, or red at one extremity and green at the other. One blue crystal found was 9 inches long. The locality affords all of the colored varieties, achroite, indicolite, and rubellite. Red and green tourmalines are found at Chesterfield, Massachusetts, in a granite vein with albite, uraninite, and pyrochlore, the crystals small and curved, nearly opaque, and fragile; green crystals, often with distinct prisms of red color inside, are found at this locality. At Goshen, Massachusetts, similar varieties occur, and the blue is met with in great perfection. At Haddam, Connecticut, in crystals in mica-slate with anthophyllite, also in granite with iolite, and also at the gneiss quarries, on the east side of the river. At Haddam Neck, in fine green, and parti-colored crystals affording magnificent gems. Near Gouverneur, New York, light and dark brown crystals, often highly modified. Good crystals are found in Chester County, Pennsylvania.

The most noted American locality for the pink and variegated tourmaline is the Mesa Grande region in San Diego County, southern California. The mineral occurs here also in pegmatitic rocks associated with the variety of spodumene commercially known as kunzite, and occasional gem minerals of other varieties. A very complete and systematic series of these pegmatites from both the Appalachian regions and California, with their associated minerals, is to be found among the rock collections in the geological hall on the first floor of the Museum. (See also pp. 136-139.)

In Canada magnificent green-yellow crystals occur in the limestone at Great Calumet Island; amber-colored ones at Fitzroy, Ontario; transparent brown at Hunterstown, Quebec; black at Bathurst and Elmsley, Ontario, and St. Jerome, Quebec. Small brilliant crystals of the black variety are found in decomposed feldspar, at Andreasberg in the Hartz. Rubellite and green tourmaline occur near Ekaterinburg in Russia. The Island of Elba yields pink, red, white, green, black, and parti-colored crystals. Brazil affords a large proportion of the specimens used for gems, and has been one of the great sources of supply for more than 200 years. Ceylon, India, and Burma produce good gem material, the latter locality affording some magnificent rubellites, rivaling the ruby in color.

LIST OF SPECIMENS.

BRAZIL.

Cabochon, triangular girdle; red and green; 59.99 carats; 28 by 10 mm....	No. 225
Step-brilliant, elliptical girdle; blue-green; 36.78 carats; 24 by 21 by 12 mm.....	No. 1118
Brilliant, rectangular girdle; green-yellow; 9.19 carats; 15 by 13 by 8 mm..	No. 1114
Step, rectangular girdle; deep green; 8.59 carats; 14.5 by 13 by 6 mm.....	No. 1115

Brilliant, rectangular girdle; pale violet-red; 5.192 carats; 11.5 by 9 by 7.5 mm.....	No. 221
Brilliant, elliptical girdle; violet-red; 5.155 carats; 14 by 9.5 by 6 mm....	No. 226
Step-brilliant, elliptical girdle; deep blue-green; 4.912 carats; 14.5 by 11 by 4 mm.....	No. 220
Step-brilliant, rectangular girdle; dull green-brown; 3.827 carats; 10 by 9 by 6 mm.....	No. 1116
Step-brilliant, rectangular girdle; deep blue-green; 2.79 carats; 10 by 8 by 4.5 mm.....	No. 223
Step-brilliant, square girdle; deep blue-green; 2.378 carats; 9 by 5 mm....	No. 222
Step-brilliant, elliptical girdle; pale yellow; 2.276 carats; 8 by 7.5 by 6 mm.	No. 1117
Step, rectangular girdle; dark green; 1.725 carats; 15 by 3.5 by 3 mm.....	No. 230
Step-brilliant, rectangular girdle; dark green; 1.5 carats; 9 by 7.5 by 3 mm.	No. 224
Step, rectangular girdle; yellow-green; 1.4 carats; 9 by 6 by 3 mm.....	No. 227
Step, rectangular girdle; yellow-green; 1.36 carats; 9 by 6 by 3 mm.....	No. 228
Step, rectangular girdle; dark green; 1.285 carats; 14 by 4 by 3 mm.....	No. 231
Step, rectangular girdle; dark green; 1.13 carats; 7.5 by 6.5 by 3 mm.....	No. 229
Step, rectangular girdle; dark green; 0.885 carats; 14 by 3 by 2.5 mm....	No. 232
Step, rectangular girdle; dark green; 0.76 carat; 12 by 3 by 2 mm.....	No. 233
Step-brilliant; rectangular girdle; violet-red; 0.515 carat; 5 by 4 by 3.5 mm.....	No. 235
Step-brilliant, square girdle; dark blue; 0.425 carat; 5 by 2.5 mm.....	No. 234
Brilliant, circular girdle; light green; 0.425 carat; 4.5 by 3.5 mm.....	No. 236

CEYLON.

Cabochon, elliptical girdle; pale green; 12.53 carats; 15 by 12 by 6.5 mm. Isaac Lea collection.....	No. 237
Step-brilliant, elliptical girdle; brown; 3.14 carats; 10 by 9 by 6 mm. Isaac Lea collection.....	No. 238
Step-brilliant, square girdle; brown; 2.749 carats; 9 by 5 mm. Isaac Lea collection.....	No. 239
Step-brilliant, elliptical girdle; brown-yellow; 2.66 carats; 8.5 by 6 by 5 mm. Isaac Lea collection.....	No. 241
Step-brilliant, rectangular girdle; brown; 1.9 carats; 7.5 by 7 by 5 mm. Isaac Lea collection.....	No. 240
Step-brilliant, rectangular girdle; red-brown; 1.06 carats; 8 by 6 by 4 mm. Isaac Lea collection.....	No. 242
Step-brilliant, elliptical girdle; orange-yellow; 0.829 carat; 6 by 5 by 5 mm. Isaac Lea collection.....	No. 243
Three gems, step-brilliant, elliptical girdle; pale orange-yellow; total weight, 1.454 carats; average size, 4 by 3 by 2 mm. Isaac Lea collection.....	No. 244

ISLAND OF ELBA.

Step-brilliant, rectangular girdle; pale red and yellow-green; 9.844 carats; 16.5 by 9.5 by 8 mm.....	No. 251

TURQUOISE.

Composition.—Copper aluminum hydrous phosphate, $\text{CuAl}_6(\text{PO}_4)_4 + 9\text{H}_2\text{O}$.

Crystallization.—Triclinic; distinct crystals rare, the mineral being almost always crypto-crystalline.

Color.—Blue, owing to the copper present.

Luster.—Vitreous; translucent to opaque.

Hardness.—6; not very durable.

Specific gravity.— 2.70 ± 0.10 .

Because of its crypto-crystalline character, turquoise will absorb grease and oils readily, and it is not, therefore, absolutely satisfactory

as a precious stone, particularly when worn as a necklace and next to the skin. Its opaque nature and robin's-egg blue color are its most pronounced characteristics, but it can be determined absolutely only by chemical tests. The only natural stone with which it is likely to become confused is variscite, likewise an aluminum phosphate. From this last it can, as a rule, be distinguished by its blue cast, variscite being green, inclined to yellowish. The mineral occurs

FIG. 13.—CHINESE CARVING
IN TURQUOISE.

as a secondary product in veins and pockets in aluminous rocks, both igneous and sedimentary. It is easily and abundantly imitated artificially, and on this and other accounts the so-called "matrix" turquoise—that is, stones including portions of the matrix—are most desirable. Turquoise is usually cut cabochon because of its opaque nature, and has been for centuries much admired as a gem, both by civilized and barbarous people. In the United States it is found only in Arizona, Nevada, and New Mexico.

--	----------

Unakite.—See under Miscellaneous (Granite) on page 120.

VARISCITE.

Synonym.—Utahlite.

Composition.—Hydrous aluminum phosphate, $\text{Al}(\text{PO}_4) + 2\text{H}_2\text{O}$.

Crystallization.—Orthorhombic; distinct crystals rare, the material being usually crypto-crystalline.

Color.—Green to blue-green, owing to the presence of chromium or vanadium, or both.

Luster.—Vitreous; translucent to opaque.

Hardness.—4; not a durable stone under ordinary conditions of wear.

Specific gravity.— 2.40 ± 0.05 .

Optical properties.—Mean refractive index, 1.55; double refraction moderate, 0.02; optically biaxial.

The mineral may be distinguished from turquoise, which it sometimes closely resembles, by its more greenish color and less hardness, and from other gems which resemble it, by chemical tests. It occurs filling fissures and cavities in rocks high in aluminum, mostly in shale or slate (pl. 13). In use it is usually cut cabochon because of its practically opaque character. Of less value than turquoise.

 Seventy-one stones, cabochon, elliptical and pear-shaped girdles; showing variation from pale green to deep green, mottled with gray and black; 25.19 to 1.6 carats; 29 by 20 by 7 to 9 by 7 by 4 mm. (figs. 1-3, 4, 6, pl. 12)..... No. 1104
 Six stones, cabochon, elliptical girdles; green mottled with gray and white; 113.15 to 56.42 carats; 45 by 35 by 12 to 35 by 25 by 10 mm. (figs. 7, 8, pl. 12)..... No. 1101

VESUVIANITE.

Variety.—Californite.

Composition.—A complex silicate.

Crystallization.—Tetragonal; habit prismatic to columnar.

Color.—May be yellow, brown, or yellow-green, depending on the state of oxidation of the iron present; pleochroism faint.

Luster.—Vitreous; translucent.

Hardness.—6.5; a fairly durable stone.

Specific gravity.— 3.40 ± 0.10 .

Optical properties.—Mean refractive index, 1.72; double refraction weak, 0.006; optically uniaxial, negative.

Vesuvianite in general is distinguished by its optical properties; californite, a deep green variety, resembles some forms of serpentine and jade; from the former it is distinguished by its much greater hardness, from the latter by the fact that it is softer, more crystalline, and has a distinctly higher index of refraction. It occurs in metamorphic rocks, chiefly in limestone. Is rarely cut as a precious stone, but the variety californite is sometimes carved or cut into slabs for ornamental purposes.

- Happy Camp, Siskiyou County:
 Thirty stones, cabochon, various girdles; green and cloudy white; total weight, 174.825 carats; 28 by 10 to 8 by 4 mm..... No. 1542

WERNERITE.

Synonym.—Scapolite.

Composition.—A complex calcium aluminum sodium chloro-silicate.

Crystallization.—Tetragonal; pyramidal; habit prismatic.

Color.—White when pure; may be colored pale violet or pale yellow by impurities of unknown composition.

Luster.—Vitreous.

Hardness.—5.5; not very durable.

Specific gravity.— 2.70 ± 0.10 .

Optical properties.—Mean refractive index 1.55; double refraction moderate, 0.01. Optically uniaxial, negative.

The mineral is distinguished by color and optical properties. Occurs chiefly in metamorphosed limestone. Because of its peculiar color it is occasionally cut cabochon, but is worth little more than the cost of cutting.

LIST OF SPECIMENS.

CANADA (TEMPLETON, QUEBEC).

Cabochon, elliptical girdle; yellow; 46.68 carats; 30 by 22 by 11 mm. Isaac Lea collection No. 593

MADAGASCAR.

Tsarasaotra Province.

Brilliant, square girdle; pale yellow; 8.2 carats; 12 by 9 mm. Isaac Lea collection No. 1818
Step-brilliant; elongated octagonal girdle; pale yellow; 5.77 carats; 12 by 10 by 7 mm. Isaac Lea collection No. 1819

WILLEMITE.

Composition.—Zinc orthosilicate, $Zn_2(SiO_4)$, with some manganese replacing the zinc.

Crystallization.—Hexagonal (trigonal), tri-rhombohedral.

Color.—Colorless when pure, but usually pale green-yellow.

Luster.—Vitreous; translucent.

Hardness.—5.5; not very durable.

Specific gravity.— 4.10 ± 0.10 .

Optical properties.—Mean refractive index, 1.70; double refraction moderate, 0.02; optically uniaxial, positive.

The high specific gravity of the mineral is a rather characteristic feature, and in color and general appearance it differs from practically every other precious stone. The only willemite thus far found suitable for cutting occurs in the zinc-ore deposit at Franklin Furnace, New Jersey. Most of the material is opaque, or only translucent, and is used as an ore of zinc; but occasional specimens are found which are clear and yield small stones, which are usually cut brilliant.

ZIRCON.

Variety.—Hyacinth.*Composition.*—Zirconium orthosilicate, $Zr(SiO_4)$.*Crystallization.*—Tetragonal, habit prismatic.*Color.*—Colorless when pure, but usually showing disperse colors, especially pale green, yellow, or brown, owing to iron and perhaps other constituents; rarely blue.*Luster.*—Adamantine; transparent.*Hardness.*—7.5; a very durable stone.*Specific gravity.*—Averaging about 4.7.*Optical properties.*—Mean refractive index 1.95; double refraction strong, 0.06; optically uniaxial, positive.

Some varieties of zircon yield with the microspectroscope a brilliant and characteristic absorption spectrum, due to the presence of small amounts of uranium in the lower state of oxidation. This spectrum consists of eight narrow bands, the strongest of which lies in the orange, the others being somewhat uniformly distributed through the whole spectrum. Specimens free from uranium, however, show no spectrum whatever, so that this is not a certain test for the mineral. The high specific gravity and refractive index are sufficiently characteristic for identification. In this last respect, indeed, the zircon resembles diamond in luster and play of colors, or "fire." It is cut faceted and rather widely used as a precious stone, although its colors are, as a rule, not particularly attractive.

ZOISITE: THULITE.

This is a massive form of a calcium aluminum silicate which is gray when pure, but often colored pink or red by traces of manganese. It is hard and quite durable and occurs in metamorphic rocks

like mica schists. Being compact and opaque, it is cut only cabochon or carved into small ornaments.

4. SUPPLEMENTAL COLLECTIONS.

1. ROUGH AND CUT STONES.

It was Dr. Leander T. Chamberlain's expressed desire that the Lea collection should consist, for the most part, of cut stones. For educational purposes, however, it seemed desirable to show in many cases the rough materials as well, since there is often a marked difference in appearance of the material in the two conditions. A

FIG. 14.—MOSS AGATES IN ROUGH AND CUT FORMS.

supplemental collection has, therefore, been established, duplicating the first in part. As at present installed this is limited to a single case, comprising the minerals listed below, the rough material and the stones cut from it being placed side by side, usually on the same block or pad.

- UNAKITE**, Milan's Gap, Madison County, Virginia. Cabochon, elliptical girdle; mottled green and pink; 55.175 carats; 36 by 29 by 7 mm. (fig. 11, pl. 7). Cut from specimen 36784..... No. 1258
- VARISCITE**, Columbus, Nevada. Fifteen stones, cabochon, mostly elliptical girdles; varying from greenish-white to green, brown, and black, mottled; 23.24 carats to 3.06 carats; 35 by 18 by 5 to 13 by 9 by 4 mm. Cut from specimen 87403..... No. 1103
- VARISCITE**, Lucin, Utah. Nine gems, cabochon, elliptical and pear-shaped girdles; green and gray, mottled; total weight, 56.79 carats; 27 by 20 by 5 to 10 by 8 by 4 mm. Cut from specimen 87416..... No. 1102

VARISCITE (AMATRICE) , Tooele County, Utah. Twelve stones, cabochon, elliptical girdle; varying from pale to dark green, mottled with brown and white; 13.67 carats to 1.94 carats; 22 by 15 by 6 to 11 by 7 by 4 mm. Cut from specimen 87402.....	No. 1105
VESUVIANITE (CALIFORNITE) , Big Bar, California. Thirty-seven stones, cabochon, various girdles; green, some with matrix; total weight, 206.65 carats; 30 by 13 by 8 to 9 by 5 mm. Cut from specimen 87409.....	No. 1539
VESUVIANITE (CALIFORNITE) , Fresno County, California. Cabochon, elliptical girdle; green; 5.88 carats; 16 by 8 by 10 mm. Cut from specimen 86945.....	No. 1541
VESUVIANITE (CALIFORNITE) , Lindsay, California. Eleven stones, cabochon, mostly elliptical girdles; green; total weight, 56.4 carats; 23 by 9 by 5 to 10 by 5 mm. Cut from specimen 87410.....	No. 1540

2. IMITATION STONES.

The basis of most imitation gems is a very brilliant lead glass known as "paste" or "strass." Imitation gems may consist of paste alone, or of part paste and part stone, as in the "doublet" and "triplet." The one is made up of a table of a genuine stone, usually off-color, cemented to a pavilion made of a paste having the approved color. The other consists of a crown, table, and pavilion made of a pale or inferior stone, with a thin layer of colored glass at the girdle.

Imitation pearls are made by coating the inner surfaces of glass beads with a preparation made from the scales of certain fishes.

AMETHYST ; eight stones, various cuts; red-violet; 25 by 13 to 10 by 7 mm..	No. 1603
AQUAMARINE ; seven stones, various cuts; green-blue; 16 by 9 by 5 to 8 by 5 mm.....	No. 1596
CARNELIAN (artificially colored chalcedony); two stones, one table, rectangular, one cabochon, circular girdle; red-brown; 20 by 15 by 3 and 16 by 7 mm.....	No. 1588
CAT'S-EYE ; cabochon, four stones, circular and elliptical girdles; various colors; 19 by 8 to 13 by 7 mm.....	No. 1581
CHRYSOPRASE (artificially colored chalcedony); three stones, cabochon, elliptical girdle; green; 14 by 10 by 4, 12 by 8 by 4, and 13 by 5 by 3 mm.....	No. 1580
DIAMOND ("Jagersfontein"); brilliant, circular girdle; colorless; 9 by 6 mm.....	No. 1590
DIAMOND ("Light canary"); brilliant, circular girdle; pale yellow; 13 by 9 mm.....	No. 1591
DIAMOND ; 25 stones, brilliant, circular girdle; 15 by 10 to 7 by 5 mm....	No. 1592
EMERALD (doublet); step-brilliant, rectangular girdle; green; 5.5 by 4 by 3 mm. Mounted in a ring. Isaac Lea collection.....	No. 827
EMERALD (triplet); two stones, step, octagon girdle; green; 8 by 5 mm..	No. 1607
EMERALD ; eight stones, step and step brilliant, circular, octagonal, and square girdles; 20 by 12 to 8 by 4 mm.....	No. 1595
GARNET ; two stones, cabochon, circular girdle; deep red; 10 by 7 and 8 by 6 mm.....	No. 1602
GEM STONE colored with uranium oxides; brilliant, circular girdle; 8 by 5 mm. Gift of Capt. Harry Bryan.....	No. 1610

HARLEQUIN STONE (artificially colored crocidolite); three stones, cabochon, circular and elliptical girdles; red, brown, and blue-gray; 16 by 7 to 10 by 5 by 4 mm.....	No. 1587
JADE ; cabochon, elliptical girdle; green; 40 by 30 by 6 mm.....	No. 1579
JADE ; cabochon, circular girdle; dark green; 16 by 7 mm.....	No. 1578
MOONSTONE ; four stones, cabochon, pendant; colorless; 26 by 16 to 22 by 10 mm.....	No. 1582
MOSS AGATE ; cabochon, rectangular girdle; light brown with dark inclusions; 19 by 12 mm.....	No. 1575
OLIVINE ; three stones, brilliant and step, circular, square, and rectangular girdles; deep green; 12 by 8, 9 by 6, and 11 by 8 by 5 mm.....	No. 1601
OPAL ; two, one round, one bulb-shaped; iridescent colors.....	No. 1586
PEARL ; four round beads, white, 12 to 8 mm. diameter.....	No. 1583
PEARL ; four round beads; steel-gray; 12 to 8 mm. diameter.....	No. 1585
PEARL ; four round beads; very pale pink; 12 to 6 mm. diameter.....	No. 1584
ROSE QUARTZ ; five stones, cabochon, various girdles; pale pink; 15 by 15 by 6 to 15 by 10 by 5 mm.....	No. 1589
RUBY (doublet); step-brilliant, circular girdle; deep red; 10 by 5.5 mm...	No. 1608
RUBY ; four stones, brilliant and step-brilliant; circular and square girdles; deep red; 13 by 7 to 8 by 4 mm.....	No. 1593
SAPPHIRE (doublet); two stones, brilliant, circular girdle; deep blue; 5 by 3 mm.....	No. 1609
SAPPHIRE ; four stones, step-brilliant, circular and square girdles; deep blue; 12 by 6 to 4 by 3 mm.....	No. 1594
TOPAZ ; three stones, step, rectangular and square girdles; pale pink; 34 by 9 by 5, 11 by 8 by 5, and 8 by 6 mm.....	No. 1599
TOPAZ ; cabochon, brilliant, and step-brilliant; various girdles; deep yellow; 27 by 16 by 10 to 9 by 7 mm.....	No. 1597
TOPAZ ; step-brilliant, elliptical girdle; very pale red-orange; 26 by 15 by 10 mm.....	No. 1598
TOURMALINE ; three stones; step-brilliant and brilliant, rectangular and elliptical girdles; deep pink; 12 by 10 by 5 to 6 by 5 by 3 mm.....	No. 1600
TURQUOISE ; 30 stones, cabochon, circular girdle; average size, 4 by 2 mm..	No. 1577
TURQUOISE (artificially colored chalcedony); two stones, cabochon, circular and elliptical girdles; blue; 16 by 6 and 20 by 6 by 3 mm.....	No. 1576

MODELS OF FAMOUS DIAMONDS.

CULLINAN , rough, and largest stone cut from it.	ORLOFF.
EMPRESS EUGENIE.	PASHA OF EGYPT.
EXCELSIOR.	PIGGOTT.
FLORENTINE.	POLAR STAR.
GREAT MOGUL.	REGENT or PITT.
HOPE.	SANCY.
KOHINOOR , before and after recutting.	SHAH OF PERSIA
NASSAK.	STAR OF THE SOUTH.

3. ARTIFICIAL OR SYNTHETIC STONES.

A sharp distinction is to be drawn between the imitation of a gem stone and its formation by artificial methods. The imitation gem only simulates the natural substance; the artificial gem is identical with it. Examples of the latter class are to be found in the diamond

as produced by heat and pressure in cast iron; the ruby as produced by the fusion of alumina with traces of chrome oxide; and the sapphire as made in a similar way.

LIST OF SPECIMENS.

- RUBY**; step-brilliant, square girdle; deep red; 1.015 carats; 5.5 by 4 mm. . . . No. 1605
RUBY; step-brilliant, elliptical girdle; deep red; 2.08 carats; 8 by 7.5 by 4.5 mm. No. 1604
SAPPHIRE; brilliant, circular girdle; pale blue; 8.98 carats; 13 by 9 mm. . . . No. 1606

4. MODELS SHOWING FORMS INTO WHICH GEMS ARE CUT.

The cutting of many gem stones is necessary for the complete development of those properties upon which their beauty largely depends. In order that the inherent properties of a gem may be developed to the maximum it should be cut and polished in that form best suited to the exhibition of its beauties. The various styles of cut represented are:

Brilliant.	Star.
Old square cut brilliant.	Portuguese.
English square cut brilliant.	Rose.
Split brilliant.	Step.
Double brilliant.	Step brilliant.
Single brilliant.	Table.

5. SMALL ORNAMENTAL OBJECTS NOT USED FOR PERSONAL ADORNMENT.

The materials listed and described below, while in some cases of the same mineralogical nature as the gems described above, are not utilized for the most part for personal adornment, but as small ornaments and works of art. Their beauty is dependent in some cases on that of the material, in others the art of the lapidary is largely responsible for their attractiveness.

AGALMATOLITE—PAGODITE.

The material known by this name is a soft stone of compact texture which may consist of pyrophyllite, an aluminum hydrous silicate, or talc, a magnesium hydrous silicate. The color is gray when pure, but often bluish, greenish, brownish, or yellowish, or mottled with different colors due to the presence of iron in various forms. The luster is dull, waxy. The material occurs usually in metamorphic rocks, chiefly crystalline schists. The commercial sources are China and Japan, where it is used extensively for carving grotesque images and objects of art which are frequently sold to the unwary under the name of jade, from which it can readily be distinguished by its softness.

LIST OF SPECIMENS.

- Vase, carved with figures of birds and flowers; green-gray with pale red tinting; 22.5 cm. high, 12.5 cm. greatest width. China. No. 1651
 Vase, carved with figure of deer, birds, and flowers; red and black mottled on dark base; 26 cm. high, 18 cm. wide. China. No. 1655

Vase, carving of vine; very pale green-gray on brown base; 25 cm. high. China.....	No. 1657
Vase, carving of leaves; red-brown and gray on brown base; 24 cm. high. China.....	No. 1658
Vase, carved human figure in branches of tree; red-brown on brown base. China.....	No. 1662
Vase, gray-green and dark brown, on brown base; 12 cm. high, 4.5 cm. wide. China.....	No. 1668
Urn with carved handles and cover; mottled red, gray, and light brown; 18 by 21 cm. China.....	No. 1659
Ornamental carved piece, deer with flowers; yellow on dark brown base; 20.5 by 90 cm. China.....	No. 1652
Carved piece, rectangular, lattice-work sides; light green-gray; 9 by 4.5 by 4 cm. China.....	No. 1667
Group of five baboons; light gray-green; 17 cm. high. China.....	No. 1653
Two Chinese priests on dark pedestals, one red mottled with gray-green; one gray-green; 22.5 cm. high. China.....	No. 1654
Three Chinese figures on end of pedestal; gray-green faintly mottled with red. China.....	No. 1656
Carving of a bird in a tree; yellow-brown. China.....	No. 1660
Small Chinese figure on a pedestal; brown-red. China.....	No. 1666
Ash tray, carved with leaves; gray; 10 by 6.5 cm. China.....	No. 1663
Ash tray, carved with small trees; red-brown and gray; 12 by 7 cm. China..	No. 1664
Ash tray; carved with leaves and fruit; red-brown and gray, 11 by 5.5 cm. China.....	No. 1665
Carved tray; red-brown and gray; 22 by 16 cm. Japan.....	No. 1661

AMAZONSTONE.

LIST OF SPECIMENS.

Two spheres; green; 40 and 37 mm. diameter; Amelia Courthouse, Virginia. Isaac Lea collection.....	No. 451
Tray; light green; 8.8 by 6.2 cm. Amelia Courthouse, Virginia.....	No. 246

CATLINITE—PIPESTONE.

This material is an indurated clay or argillite. The prevailing colors are dull reddish, often more or less mottled with white. It occurs in Minnesota and South Dakota intercalated with other sedimentary rocks and was formerly used by the Sioux Indians for the making of pipes, and more recently has been used for small ornaments and paper weights. It is soft and readily carved.

LIST OF SPECIMENS.

Indian head carved on rectangular block; dull red; Minnesota.....	No. 1760
Indian pipe. Minnesota.....	No. 1759

CHALCEDONY.

LIST OF SPECIMENS.

Paper weight, pentagonal dodecahedron; blue (artificially colored); 6.5 cm. Isaac Lea collection.....	No. 1761
Snuff box; blue (artificially colored); 42 by 30 mm.....	No. 1773
Carved handle; very pale pink; 5.8 cm. long.....	No. 1777

CHALCEDONY, variety AGATE.

Thin polished slab gray with green inclusions; 14.5 by 9.5 cm. Brazil.....	No. 1733
Cube with truncate edges; red and gray; 5 cm. Brazil.....	No. 1716
Penholder; brown and white banded; 16.9 cm. long. Germany. Isaac Lea collection.....	No. 1717
Seal handle; brown; 5.7 cm. long. Germany. Isaac Lea collection.....	No. 1736
Cane head; red, banded; 5.2 cm. long. Germany. Isaac Lea collection...	No. 1737
Seven snuff boxes; various colors and sizes. Oberstein, Prussia. Isaac Lea collection.....	No. 1772
Dish; brown, banded with white; 10.7 by 9 cm. Oberstein, Prussia. Isaac Lea collection.....	No. 1731
Dish; red, banded; 8 by 6.2 cm. Oberstein, Prussia. Isaac Lea col- lection.....	No. 1718
Seal handle, carved; black, banded with white; 8.3 cm. long. Oberstein, Prussia.....	No. 1734
Cube; brown; 4 cm. Oberstein, Prussia.....	No. 1757
Cube with truncated edges; black, banded with white; 4.5 cm. Isaac Lea collection.....	No. 1758
Two spheres; brown and white banded; 7.7 and 5.4 cm. diameter.....	No. 1763
Seal handle; brown, banded; 8.6 cm. long. Gift of Dr. Robert Fletcher...	No. 1738
Paperweight, with round knob engraved with human face; dark brown; 12.3 by 8.3 cm.....	No. 1726
Dental tools (four) and mixing slab; gray and brown. Gift of Alexander A. Anzell.....	No. 1700
Book; brown and black with white banding; 10 by 5.5 cm.....	No. 1721
Card case; agate covers mounted on leather; colorless, red and yellow banded; 8.5 by 5.5 cm. Bequest of William H. Forwood.....	No. 1774
Paper knife; red banded; 15 cm. long. Bequest of William H. Forwood...	No. 1775

CHALCEDONY, variety BLOODSTONE.

Two snuff boxes: green mottled with red; 40 by 25 mm. India.....	No. 1461
--	----------

CHALCEDONY, variety CARNELIAN.

Elliptical slab; red and yellow; 12 by 10 cm.....	No. 505
Paper cutter; red; 14.8 cm. long. Brazil.....	No. 504

CHALCEDONY, variety JASPER.

Paper weight; red and yellow; 16.5 by 10 by 1.9 cm. Orenburg, Ural Mountains, Russia.....	No. 1713
Paper weight; green and red; 9 by 6.3 cm. Siberia.....	No. 1714
Small carved piece, monument-shaped; green, red, and dark gray; 9.7 cm. high.....	No. 1739

CHALCEDONY, variety MOSS AGATE.

Paper cutter; green and gray; 35 cm. long. Germany. Isaac Lea col- lection.....	No. 1720
--	----------

CHALCEDONY, variety SILICIFIED WOOD.

Sphere; violet red and red, banded; 11 cm. diameter. Chalcedony Park, Arizona.....	No. 1767
Dish; brown mottled; 12.5 by 8.5 cm. Chalcedony Park, Arizona.....	No. 1732
Four polished slabs; red predominates; 21 by 15.5, 21 by 12, 17 by 16.5, 16.5 by 9.4 cm. Chalcedony Park, Arizona. Gift of The Drake Company.	No. 1682

Polished slab; gray; 17 by 17 cm. Chalcedony Park, Arizona.....	No. 1688
Mosaic slab; 25 by 25 cm. Chalcedony Park, Arizona.....	No. 1683
Rectangular paper weight; brown; 6 by 5 by 2.5 cm. Humboldt County, Nevada.....	No. 1684
Paper weight; yellow and red-brown, and gray; 10.2 by 7 by 2 cm.....	No. 1685
Cube; gray and white streaked; 5 cm.....	No. 1686
Carved dog's head; pink and yellow. Chalcedony Park, Arizona. Gift of Maj. J. W. Powell.....	No. 1687

COAL.

Rectangular slab carved with a bunch of flowers; 15 by 10.5 cm.....	No. 1735
---	----------

CROCIDOLITE.

LIST OF SPECIMENS.

Paper weight; dark blue-black; 11 by 8 cm. Griqualand, South Africa....	No. 1744
Dish; brown in white quartz; 13 by 9 cm. Griqualand, South Africa.....	No. 1745
Half sphere; brown; 5.5 cm. diameter; Griqualand, South Africa. Isaac Lea collection.....	No. 1746
Sphere; brown; 3.8 cm. diameter. Griqualand, South Africa.....	No. 1747

FLUORITE.

LIST OF SPECIMENS.

Cup on black marble base; dark purple; 10 cm. diameter. England.....	No. 1754
Two ash trays; mottled; 8.7 and 8.5 cm. England.....	No. 1755

GRAPHIC GRANITE—PEGMATITE.

This is a variety of pegmatite in which the quartz and feldspars have crystallized in long, parallel prisms which on cutting at right angles to the axis of elongation give rise to peculiar figures suggestive of letters of the Phoenician alphabet, hence the name *Graphic*. The light color and slight contrast of the two principal minerals render the material of little interest from a gem standpoint, but of considerable interest when cut into ornaments.

LIST OF SPECIMENS.

Ash tray; light brown; 14 by 8.2 cm. Siberia.....	No. 1727
Sphere; gray and white; 7 cm. Auburn, Maine.....	No. 1769

GYPSUM, variety SATINSPAR.

LIST OF SPECIMENS.

Goose egg; white; 9.5 cm. long. Bridgeford, England.....	No. 1669
Sphere; white; 6.5 cm. diameter.....	No. 1722

JADE.

LIST OF SPECIMENS.

Paper weight in form of a lotus leaf; dark green; 15 by 6 cm. China.....	No. 1701
Carving in the form of a vase; gray-green; 14 cm. long. China.....	No. 1702
Inkstand on a base of teak; light green. China.....	No. 1705
Vase on a base of teak; gray-green; 11.5 cm. high. China.....	No. 1704
Small bird mounted on gold stand; light green. China.....	No. 1703

LABRADORITE.

LIST OF SPECIMENS.

Medallion of a knight's head; gray, blue, green, etc., in play of colors; 10.5 by 7.5 cm. Labrador	No. 1750
Small monumental shaped object; gray; 10 cm. high. Labrador.....	No. 1749

LEPIDOLITE.

A lithia mica of a pink color and sometimes sufficiently compact to be carved into small ornaments. It occurs associated with gem minerals (tourmaline) in the pegmatite quarries of Maine, California, and elsewhere.

LIST OF SPECIMENS.

Ash tray; rectangular; violet-red; 9 by 4.7 by 1.3 cm. Rozena, Moravia. Gift of C. S. Bement.....	No. 1748
--	----------

MALACHITE.

LIST OF SPECIMENS.

Cube with truncated edges; green; 5 cm. Morenci, Arizona.....	No. 1696
Composite slab; green; 11 by 8.5 cm. Ural Mountains.....	No. 1697

MARBLE, CALCITE, and ARAGONITE.

Calcium carbonate occurs in nature under a great variety of forms, usually included under the mineralogical names of calcite and aragonite, or occurring in large rock-like masses as limestone and marble. The last named forms are used extensively in building and the finer grades (marble) for decorative work, statuary, and ornaments. Travertine, cave marble, and onyx marble are the names given to deposits on the surface or in caves and crevices in limestone, from water solutions. These are sometimes of exceptional beauty. The so-called oriental alabaster used by the ancient Egyptians was a travertine found in caves and fissures in the Eocene limestone of Egypt. Lumachelle is a name given to a variety in which the included shell fragments still retain their original nacreous or pearly luster. Other varietal names are given according to origin, color, and structure. These are to be found in the collection of building and ornamental stones. (See also under coral and pearl, pp. 31 and 77.)

LIST OF SPECIMENS.

Sphere of onyx marble; green-yellow; 9 cm. diameter. Big Buck Creek, Arizona.....	No. 1766
Sphere of travertine; pale yellow; 7.8 cm. diameter. Yavapai County, Arizona.....	No. 1765
Carving of a dragon on black limestone. Japan.....	No. 1689
Sphere of marble; brown and gray; 8 cm. diameter. Japan.....	No. 1770
Paper knife of onyx; 19.2 cm. long. Puebla, Mexico.....	No. 1715

Paper weight of onyx with irregular oval handle; base white, handle red-brown, mottled; 8 by 5.5 cm. Puebla, Mexico.....	No. 1835
Carved ornament in imitation of fruit; banded onyx; 6.7 cm. diameter. Mexico.....	No. 1751
Model of mounted cannon of stalagmite. Rock of Gibraltar.....	No. 1692
Paper weight of onyx; pale green; triangular; 6.5 cm. Near Upper Soda Spring, Siskiyou County, California.....	No. 1691
Paper weight of fossil coral; gray; 8.5 by 7.5 by 4.5 cm. Iowa.....	No. 1699
Paper weight of fossil coral; gray-brown; 7.9 by 6.5 by 3.4 cm. Iowa.....	No. 1834
Paper weight of fossil coral; dark gray brown; 5.7 by 3.9 by 2 cm. Gift of E. F. Boss.....	No. 1693
Paper weight; brown, mottled; 11 by 6.5 cm. Colusa County, California..	No. 1724
Conch shell with cameo engraved on one side; white and brown. West Indies.....	No. 1752

MOSAIC.

Jewel box of rhodonite, aventurine quartz, agate, and jasper mosaic; square and diamond shaped pieces. Material obtained in the Urals.....	No. 1708
Mosaic slab of the 17th century, made of agate and lapis-lazuli. Russia... ..	No. 1707
Mosaic paper weight made of agate, quartz, jasper, etc. Russia.....	No. 1706

FIG. 15.—LIZARD CARVED IN OPAL ON LIMONITE.

OPAL.

LIST OF SPECIMENS.

Carving of a lizard on a base of limonite; blue. Queensland, Australia (fig. 15).....	No. 1043
Paper weight; pale yellow; 5.7 by 2.3 cm. Noto, Japan.....	No. 1743

QUARTZ.

LIST OF SPECIMENS.

Polished elliptical slab inclosing rutile needles; 12.2 by 9.5 by 1.5 cm. Madagascar.....	No. 1753
Two small prisms inclosing hairlike tremolite needles; 50 by 10 and 45 by 23 mm. Isaac Lea collection. Japan.....	No. 1672
Carved seal handle of pale yellow quartz, inclosing rutile needles; 64 by 40 mm.....	No. 1681
Seal handle of amethyst; red-violet. Germany. Isaac Lea collection....	No. 1694
Small basin of beekite carved in a mass of fossil coral; yellow. Devon, England.....	No. 1756
Knife handle of citrine quartz; yellow; 7.5 cm. long. Switzerland.....	No. 1680
Carved turtle of rock crystal; colorless. Japan. Isaac Lea collection.....	No. 1677
Carved seal of rock crystal; colorless; 7 cm. long. Mursinsk, Russia.....	No. 1671
Carved eagle; colorless; 58 mm. Siberia.....	No. 1670
Drawer knob of rock crystal; colorless; 61 by 18 mm. Siberia.....	No. 1678
Knob of rock crystal; colorless; 57 by 6 mm. Switzerland.....	No. 1679

Arrow heads of rock crystal; colorless; 15 specimens, average size 40 mm. long. Red Hill, near Bakersville, North Carolina. Isaac Lea collection..	No. 245
Sphere of rock crystal; colorless; 11 cm. diameter. Chestnut Hill Township, Ashe County, North Carolina. Isaac Lea collection.....	No. 1673
Sphere of rock crystal; colorless; 7.3 cm. diameter.....	No. 1674
Sphere of rock crystal; colorless; 48 mm. diameter.....	No. 167
Three small spheres of rock crystal; colorless; 25 mm. diameter.....	No. 1676
Seal handle of rock crystal; colorless; 4.4 cm. long. Bequest of William H. Forwood.....	No. 1778
Sphere of rose quartz; pale pink; 42 mm. diameter. Albany, Oxford County, Maine. Isaac Lea collection.....	No. 1728
Seal handle of smoky quartz; dark brown; 5.5 cm. long. Australia.....	No. 1695

RHODONITE.

LIST OF SPECIMENS.

Ash tray; red with black inclusions; 14.5 by 8.2 cm. Ural Mountains.....	No. 1729
Polished slab; red; 11 by 7.7 cm. Ural Mountains.....	No. 1730

SERPENTINE.

LIST OF SPECIMENS.

Carving of an antique lamp; dark and light green. Newburyport, Massachusetts. Isaac Lea collection.....	No. 1776
Sphere; green; 5.9 cm. diameter. Montville, New Jersey.....	No. 1771
Diamond-shaped slab; green; 10.8 by 7.1 by 3.5 cm. Near Montville, New Jersey.....	No. 1762
Cylindrical paper weight; dark green; 6.5 by 2.7 cm. Lizard Point, Cornwall, England.....	No. 1742
Vase; green-gray with black veins; 20 cm. high. Gift of W. H. Abbott....	No. 1698
Monument-shaped piece of bowenite; light green; 6.5 by 4 by 2.2 cm. Smithfield, Rhode Island.....	No. 1690
Sphere; green and white banded; 7.2 cm. diameter. Gila Bend, New Mexico.....	No. 1768

SOAPSTONE.

LIST OF SPECIMENS.

Paper weight; mottled green and brown; 8.2 by 8.2 cm. Santa Catalina Island.....	No. 1725
Circular box with cover; mottled green and brown; 8.8 cm. diameter. Santa Catalina Island.....	No. 1740
Three turned cups; dark green. Santa Catalina Island.....	No. 1741

TALC.

LIST OF SPECIMENS.

Carving of a turtle; green-gray. India.....	No. 1711
Box, carved; green-gray; 12.5 by 8.5 cm. India.....	No. 1710
Small bottle; green-gray; 6 by 3.7 cm. China.....	No. 1712

UNCLASSIFIED.

Carvings of fruits mounted on a tablet: Red currants, carnelian; white currants, rock crystal; blackberries, black chalcedony and serpentine; raspberries, rhodonite and amethyst; red cherries, carnelian; black cherries, black chalcedony; leaves, serpentine; base, jasper and black chalcedony. Ekaterinburg, Russia.....	No. 1709
--	----------

6. OCCURRENCE AND ASSOCIATION OF PRECIOUS STONES.

Under this heading are included exhibits designed to illustrate the occurrence and association in nature of the various stones described in the preceding pages. These are (1) a comparatively small miscellaneous collection of specimens from various sources showing the rough gem material embedded in or associated with other minerals as found; (2) a larger collection arranged in what is known as an American case, and comprising the Gardner F. Williams collection illustrating the occurrence of the diamond in South Africa; (3) the granite pegmatites and their associated minerals from the eastern United States and southern California, the last named exhibited in the Geological Hall on the first floor.

1. MISCELLANEOUS SERIES.

This comprises two cases in one of which is shown a variety of gem minerals, including both precious and semiprecious stones, either in the matrix or in the rough state as found in nature. The other contains precious opal in the matrix and includes examples from Australia and Mexico, as well as from the more recently discovered field in Humboldt County, Nevada, which furnishes a great variety of colors, ranging from the so-called "black opal" to the pale, iridescent shades.

2. DIAMOND-BEARING ROCKS OF SOUTH AFRICA.

The South African collection comprises about 100 specimens of rocks and mineral concentrates typical of the mines, together with illustrations in the form of photographs and engravings. Below is given a transcript of the label accompanying the collection.

SOUTH AFRICAN DIAMOND MINES.

[Collections illustrating the occurrence of diamonds in the De Beers Consolidated Mines (Ltd.), Kimberley, South Africa. Gift of Mr. Gardner F. Williams.]

The country rock immediately below the surface soil is an olivine diabase, locally called basalt (specimen no. 75898). Below this is a dark shale (specimen no. 75902) which is succeeded by a melaphyr (specimen no. 75910), and this by quartzite (specimen no. 75920). Through all of these have been extruded the diamond-bearing peridotite-breccia, shown in its fresh condition in specimen no. 75,933, and in the decomposed condition known as "blue ground" in specimen no. 75,932. The diamonds are now regarded as having originated through the condensation of metallic carbides in the peridotite while at a great depth below the surface, and to have been brought up in the magma to their present position at the time of its intrusion. In specimen 87701 is shown a cavity from which was removed a large crystal. There are also shown a cast of a diamond crystal weighing 363 carats and several small very perfect crystals and rounded bits (bortz) of genuine diamonds.

SOUTH AFRICAN DIAMOND MINE.

LIST OF ROCKS FROM THE SOUTH AFRICAN DIAMOND MINES IN THE GARDNER F. WILLIAMS COLLECTION.

[From De Beers Consolidated Mines (Ltd.), Kimberley.]

Below is given a complete list of the rocks from the various shafts together with the depths below the surface at which they were found to occur:

DU-TOITS-PAN SHAFT.

Museum number.	Kind of rock.	Position in shaft.
		<i>Fect.</i>
75897	Decomposed basalt.....	19- 52
75898	Hard basalt.....	52- 94
75899	Coarse grained basalt.....	94-121
75900	Fine grained basalt.....	121-125
75901	Gray shale.....	125-132

3. GRANITE PEGMATITES AND THEIR ASSOCIATED MINERALS.

The term "pegmatite" is applied to an interesting and peculiar type of igneous rock which occurs in the form of intrusive dikes and sheets, and is characterized as a rule by a coarse and extremely variable crystallization. The granite pegmatites consist for the most part of the same minerals as compose ordinary granite—that is, of quartz and feldspar, with or without mica—but are often accompanied by a considerable number of accessory minerals, which make them favorite hunting grounds for the collector. Crystallization sometimes takes

place on a gigantic scale, even to the formation of individuals several feet in length, though as a rule much smaller. At times the quartz and feldspar crystallize contemporaneously in long, parallel, skeleton, and enfolding prisms, giving rise to forms which when cut across resemble ancient Greek or Phoenician characters. Such forms are called *graphic granite*. The quartz and feldspar of the pegmatites are mined for use in pottery manufacture, the mica for electric and other purposes, while the beryls and the tourmalines, if of good color, are utilized as gems.

The pegmatites are common features of granitic rocks, and are found in greater or less abundance in nearly all of the states along the Appalachian chain, as well as in many of the regions west of the front range of the Rocky Mountains.

Two collections of these interesting rocks are shown, one from the Appalachians of the eastern United States, and one from the celebrated gem regions of southern California. Each comprises upward of 100 specimens showing the rocks in the rough and cut and polished conditions, and the associated minerals. In each case, and in the California series in particular, space is given to the decomposed and disintegrated material from the middle or "pay streak" portion together with examples of the same amount of material separated into its component minerals. The gem minerals from the California region, it should be mentioned, are mainly tourmalines of a pink and green color, and the variety of spodumene known as kunzite. Those from the Appalachians are mainly green tourmaline and the variety of beryl known as aquamarine.

A. THE APPALACHIAN PEGMATITES.

Among the more prominent objects in the Appalachian series are several large specimens showing (1) a pegmatite intrusion some 6 inches in width in gneiss, from Auburn, Maine (39058), (2) one of similar nature, 4 inches in width, bordered by a thin black tourmaline, in granite, from Cape Elizabeth, Maine (62508), (3) a thin zone of pegmatitic material with very obscure outlines in the Rockport, Massachusetts, granite (38757). There is also a large rough pegmatite from Amelia, Virginia (88983), and a fine large polished slab from Auburn, Maine (74795), cut across the grain, showing to advantage the "graphic" structure. Among the smaller and associated minerals are crystals of muscovite, showing the characteristic hexagonal outline (62377), masses of the lithia mica, lepidolite (90229), and the feldspar orthoclase or microcline (49700), amazonstone (48721), and albite (48723); also large masses of black tourmaline (89944); green radiating tourmaline in matrix (82268, 89939) and examples of beryl (90244), including the variety emerald in matrix from North Carolina (53778). The gem minerals (90223) occur associated mainly

with the albitic feldspar and the lepidolite, as in the examples from Portland, Connecticut.

Other associated minerals shown are lithiophilite from Grafton, New Hampshire (88253); apatite from Strafford, New Hampshire (87435); allanite from Crown Point, New York (90262); gadolinite from Barringer Hills, Texas (88442); and uraninite from Mitchell County, North Carolina (59329).

B. THE MESA GRANDE, CALIFORNIA, PEGMATITES.

The California series was prepared with great care and elaboration by Dr. W. T. Schaller, of the United States Geological Survey and at the same time honorary custodian of gems and precious stones in the National Museum. The details of the collection as given by him are as follows:

The nearly flat-lying pegmatite dikes, from which most of the specimens shown were obtained, crop out on the hills north and east of Pala, San Diego County, California, and are of the compound, unsymmetrical type whose different parts are thought to be due to differentiation processes rather than to multiple injections of material into reopened fissures. The upper portion of the dike is locally known as the "top rock" (nos. 89549, 89550) and is a mixture of a coarse, granular aggregate of quartz and feldspar and of a graphic pegmatite. No gem stones are found in this "top rock." The lower portion of the dikes, locally called the "bottom rock" (no. 88551), is a much finer grained granular quartz-albite rock characterized by numerous wavy bands of brownish-red garnets. These bands lie nearly horizontal in their general trend, being parallel to the slight dip of the dike. The "bottom rock" is likewise free from gem stones, but both it and the "top rock" are of great interest from the scientific point of view. Between the "top rock" and the "bottom rock" is the middle portion, called the "pay streak" by the miners, in which the gem minerals of value are found. Here also occur the cavities or pockets which often yield an abundance of the well-crystallized minerals shown in the exhibit.

The top horizontal shelf on the south side of the exhibition case contains the granitic (no. 89871) and gabbro country rock (no. 88556) and also the partly altered gabbro—a loose, friable rock—and the completely altered gabbro (no. 89856), which as a brown iron-stained clay has been washed into the cracks and seams of the pegmatite rock. Where such a crack extends into a pocket the clay has coated the gems and associated minerals found therein. There are shown, for example, white feldspars of the pegmatite coated with the brown clay derived from the gabbro country rock. The origin of the clay of the gem pockets is thus explained.

The second horizontal shelf on the south side contains different varieties of the "top rock," consisting of graphic pegmatite and granular pegmatite. The third horizontal shelf shows the mineral aggregates of the middle part or "pay streak," which yields on decomposition the loose, friable material forming the gem pockets. This same shelf also shows examples of the banded "bottom rock."

The sloping shelf on the south side contains large specimens of the different varieties of the pegmatite rock, including granular, graphic, and banded pegmatites. Several of these larger specimens have been sawed and polished and are well adapted for use as an ornamental stone, especially when cut obliquely so as to form wavy lines and circular effects resembling bird's-eye wood. One specimen in particular consists of a large section of the entire pegmatite dike and shows the aggregate of lithium minerals in the upper portion or "top rock," the granular pegmatite of the middle portion, and the banded "bottom rock." (No. 88560.)

The sloping shelf on the north side of the case illustrates the mineral contents of the gem pockets. A sample of the gem-bearing clay or pocket material is first shown, below which is an equal amount of similar gem clay separated into its constituent minerals; thus the relative proportions of the gem tourmaline, the clay washed into the pocket from the decomposed gabbro country rock, and the various minerals associated with the gem tourmaline are exhibited. For example, the pocket material from the Tourmaline King mine (no. 90312 and 90308), at Pala, shows much lepidolite, orthoclase, clay, and gem tourmaline (pink and green), and smaller amounts of muscovite and quartz. Similar gem-bearing clay from the Tourmaline Queen mine, at Pala (no. 90307), shows, in addition to much pink tourmaline, large amounts of clay, quartz, albite, and cookeite, but practically no orthoclase. A gem pocket from the Ed. Flethcher, jr., mine, at Pala (no. 90310), shows, in addition to much pink tourmaline, clay, and albite, a considerable amount of lepidolite, with only a little orthoclase. A gem pocket from the Pala Chief mine, at Pala (no. 90310), shows considerable gem kunzite, with lepidolite, quartz, clay, cookeite, and orthoclase, and smaller amounts of albite and muscovite. A similar pocket from the Caterina mine at Pala (no. 90311) shows only spodumene, pink clay, and quartz. The exhibit also includes a pocket containing an abundance of small blue tourmalines; a small pocket from the Tourmaline King mine, very rich in gem tourmalines; and several pockets free from any gem stones. Such pockets are known by the miners as "dead ones."

On this same sloping shelf are shown also several large specimens of the minerals associated with the gem pockets. Among these minerals may be noted a fine example of orbicular muscovite, an altered perthite (feldspar) crystal, a large amblygonite crystal, and several specimens of spodumene (kunzite) in the matrix. These kunzite specimens are very difficult to collect, as in general the matrix of the kunzite is so friable that it breaks to pieces when it is taken out of the mine.

The three horizontal shelves above the sloping shelf on the north side of the case contain well-developed and well-crystallized specimens of the different minerals found in the gem-pocket zone of the pegmatite dikes. Among these minerals may be noted in particular a good series of the various forms of lepidolite (nos. 88528, 88536) (including several well-crystallized specimens) (no. 89865), crystals of muscovite, fine tourmaline crystals (nos. 88165, 88166), albite and orthoclase in well-developed crystals, pink beryl (no. 89170), stilbite, cassiterite, a large crystal of lithiophilite bismuth, bismuthite, bismuthosphaerite, purpurite, hematite, and pyrite, apatite, pucherite, topaz, manganotantalite, a fine example of clear pink kunzite in the matrix (nos. 88538 and 90027), and the phosphate minerals first found in this locality, namely, palaite, salmonsite, and sicklerite.

APPENDIX 1.

THE CUTTING OF GEM STONES.

The cutting of gem stones is necessary for the complete development of those properties upon which their beauty largely depends. Rarely does the stone, as found in nature, present those qualities which make it attractive to the eye. In its natural state it is often opaque, dull, or flawed, and even if transparent and flawless its form is rarely adapted to the display of those characters which distinguish the fashioned stone. Occasionally a stone may, without artificial treatment, show to a sufficient degree those qualities which give it rank; but such cases are rare, and in order that its inherent beauty may be developed to the maximum it must be cut and polished.

The several styles of cut may all be brought under one or the other of the following heads: I. Those bounded by plane surfaces only. II. Those bounded by curved surfaces only. III. Those bounded by both curved and plane surfaces. The several examples under the above heads may be tabulated thus:

I. Bounded by plane surfaces:

- Brilliant cut.
- Double brilliant or Lisbon cut.
- Half brilliant or single cut.
- Trap or split brilliant cut.
- Portuguese cut.
- Star cut.
- Rose cut, or briolette.
- Step brilliant or mixed cut.
- Table cut.

II. Bounded by curved surfaces:

- Double cabochon cut.
- Single cabochon cut.
- Hollow cabochon cut.

III. Bounded by curved and plane surfaces—mixed cabochon cut.

BRILLIANT CUT.

The brilliant cut may be described as two truncated pyramids, placed base to base. The upper pyramid is called the *crown*, and is so truncated as to give a large plane surface; the lower one, called the *pavilion*, terminates almost in a point. The line of union of the two pyramids is called the *girdle*, and is the widest part of the stone. This fashion of cut, though occasionally modified as to the size, mutual proportions, and even the number of facets, requires, when perfect, 58 facets. The uppermost facet is called the *crown*, and is formed by removing one-third of the thickness of the fundamental octahedron; the lowermost facet is called the *culet*, or *collet*, and is formed by

removing one-eighteenth of the thickness of the stone (*a* and *b*, in text fig. 16). The triangular facets touching the table (*s* in *c*, fig. 16) are called *star facets*; those touching the girdle fall into two groups, *skill facets* (*E* in *c*) and *skew facets* (*D* in *c*). The corner facets touching the table and girdle on the crown (*B* in *c*), and the culet and girdle on the pavilion (*Q* in *d*) are called *quoins*. The facets between the quoins, and touching the table and girdle when on the crown, and the culet and girdle when on the pavilion, are called, respectively, *bezel*

FIG. 16.—THE BRILLIANT. *a* and *b*, MANNER IN WHICH THE BRILLIANT IS DERIVED FROM THE FUNDAMENTAL FORM; *c*, *d*, AND *e*, TOP, SIDE, AND BACK VIEWS OF BRILLIANT WITH 58 FACETS; *f*, *g*, AND *h*, TOP, SIDE, AND BACK VIEWS OF MODIFIED BRILLIANT WITH 66 FACETS.

facets (*A* in *c*) and *pavilion* facets (*P* in *d*). The total number of facets are distributed as follows: 1 table, 16 skill facets, 16 skew facets, 8 star facets, 8 quoins, 4 bezel facets, 4 pavilion facets, and 1 culet, as shown in *c*, *d*, and *e* of the text figures, representing the top, side, and bottom views of a brilliant with 58 facets. Occasionally the cut is modified by cutting extra facets around the culet, making 66 in all.

The brilliant cut is especially applied to the diamond, and when perfect should be of the following proportions: From the table to the

girdle, one-third, and from the girdle to the culet two-thirds of the total. The diameter of the table should be four-ninths of the breadth of the stone. When applied to other stones these proportions are more or less modified to suit their individual optical constants.

DOUBLE BRILLIANT CUT.

The double brilliant, or Lisbon cut, is a form with two rows of lozenge-shaped facets, and three rows of triangular-shaped facets,

FIG. 17.—THE DOUBLE BRILLIANT. TOP (a), SIDE (b), AND BACK (c) VIEWS.

74 in all. The figure shows top (a), side (b), and bottom (c) views of this fashion.

HALF BRILLIANT CUT.

The half brilliant, single, or old English cut is the simplest form of the brilliant, and is generally employed for stones too small to admit

FIG. 18.—THE HALF BRILLIANT. TOP (a), AND SIDE (b) VIEWS OF THE HALF BRILLIANT. IN c THE TOP IS CUT IN THE FORM OF A STAR, THEN CALLED ENGLISH SINGLE-CUT.

of numerous facets. The figure shows top (a) and side (b) views of this style of cut. Occasionally the top is cut so as to form a star (c in fig. 18) and then called English single-cut.

FIG. 19.—THE TRAP BRILLIANT. TOP (a), SIDE (b), AND BACK (c) VIEWS.

TRAP BRILLIANT CUT.

The trap brilliant, or split brilliant, differs from the full brilliant in having the foundation squares divided horizontally into two triangular facets, making 42 in all.

PORTUGUESE CUT.

The figures show the top, side, and bottom views of the Portuguese cut, which has two rows of rhomboidal and three rows of triangular facets above and below the girdle.

FIG. 20.—THE PORTUGUESE CUT. TOP (a), SIDE (b), AND BACK (c) VIEWS.

STAR CUT.

The figures show the front and back views of the star cut. The table is hexagonal in shape, and is one-fourth of the diameter of the

FIG. 21.—THE STAR CUT. FRONT (a), AND BACK (b) VIEWS.

stone; from the table spring six equilateral triangles, whose apices touch the girdle, and these triangles, by the prolongation of their points, form a star.

ROSE CUT.

The rose cut differs from the brilliant cut in that the crown consists of triangular or star facets, whose apices meet at the point or

FIG. 22.—THE ROSE CUT (a) AND (b), TOP AND SIDE VIEWS; (c) SIDE VIEW OF DOUBLE ROSE.

crown of the rose. The base lines of these star facets form the base lines for a row of skill facets whose apices touch the girdle, leaving

spaces which are each cut into two facets. The base may be flat or the bottom may be cut like the crown, making a double rose or briolette cut. The shape of a rose-cut stone may be circular, oval, or indeed any other that the rough gem may permit.

TRAP OR STEP CUT.

In the trap or step cut the facets run longitudinally around the stone from the table to the girdle and from the girdle to the culet. There are usually but two or three sets of step facets from the table

FIG. 23.—UPPER AND UNDER SIDES OF TRAP CUT.

to the girdle, while the number of steps from the girdle to the culet depends upon the thickness and color of the stone. The fashion is best adapted to emeralds and other colored stones.

STEP BRILLIANT OR MIXED CUT.

Here the form from culet to girdle is the same as that of the trap cut, while from the girdle to the table the stone is brilliant cut, or the opposite.

FIG. 24.—THE STEP BRILLIANT CUT.

TABLE CUT.

The table cut consists simply of a greatly developed table and culet meeting the girdle with beveled edges. Occasionally the S edge facets are replaced by a border of 16 or more facets.

FIG. 25.—TOP AND SIDE VIEWS OF TABLE CUT.

CABOCHON CUT.

The cabochon cut is usually applied to opaque, translucent, deep colored, or chatoyant stones. The double cabochon is usually cut

with a smaller curvature on the base than on the crown. The single cabochon is a characteristic cut for the turquoise. The hollow cabochon is adapted to very deep-colored transparent stones. The

FIG. 26.—THE CABOCHON CUT. *a*, THE SINGLE CABOCHON; *b*, THE DOUBLE CABOCHON; *c*, THE HOLLOW CABOCHON; *d*, FLAT OR TALLOW TOP CABOCHON; *e*, MIXED CABOCHON.

mixed cabochon has either the edge or side faceted, or both. In all of the cabochon cuts the arches may be of a varying degree of flatness, depending upon the nature of the stone.

CAMEO AND INTAGLIO.

The term "cameo" is applied to any engraving in relief upon the surface of a gem, usually upon a stone like onyx or a shell composed of layers of different colors, the engraving being of sufficient depth to expose the underlying layers and producing the desired contrast. An intaglio differs in being an incised engraving and usually upon a stone of uniform color throughout.

APPENDIX 2.

GEMS MENTIONED IN THE BIBLE.

The Bible contains three lists of gems. The first of these is an account of the jewels on the *ephod* of Aaron. The *ephod* is described as having a front part and a back part fastened at each shoulder with an onyx mounted in gold and engraved with the names of the children of Israel, six on each stone, to memorialize the Lord of the promise made to them. (Exodus xxviii, 6, 12, 29.) The breastplate was made of the same material as the *ephod*, and folded so as to form a kind of a pouch in which the Urim and Thummin were placed. (Exodus xxxix, 9.) The external part of this gorget, or "breastplate of judgment," was set with four rows of gems, three in each row, each stone set in a golden socket and having engraved upon it the name of one of the twelve tribes of Israel. (Exodus, xxviii, 17-20.)

The following lists taken from Biblical antiquities by Adler and Casanowicz¹ give the names of these stone in the original and in the Septuagint, together with the meaning adopted by most authorities, the rendering of the Revised Version, both in text and margin being added in parentheses:

1. <i>Odem</i> (<i>sardion</i>), carnelian (<i>sardius</i> , ruby).	2. <i>Pitdah</i> (<i>topazion</i>), topaz or peridot.	3. <i>Bareketh</i> (<i>smaragdos</i>), smaragd or emerald (<i>carbuncle emerald</i>).
4. <i>Nofek</i> (<i>anthrax</i>), carbuncle, probably the Indian ruby (emerald, carbuncle).	5. <i>Sappir</i> (<i>sapfeiros</i>), sapphire or lapis lazuli (<i>sapphire</i>).	6. <i>Yahalom</i> (<i>iaspis</i>), onyx, a kind of chalcedon (<i>diamond, sardonyx</i>).
7. <i>Leshem</i> (<i>ligyrion</i>), jacinth, others, sapphire (<i>jacinth, amber</i>).	8. <i>Shebo</i> (<i>achates</i>), agate.	9. <i>Achlamah</i> (<i>amethystos</i>), amethyst.
10. <i>Tarshish</i> (<i>chrysolithos</i>), chrysolite, others, topaz (<i>beryl, chalcedony</i>).	11. <i>Shoham</i> (<i>beryllion</i>), beryl (<i>onyx, beryl</i>).	12. <i>Yashpeh</i> (<i>onychion</i>), jasper.

In many instances the equivalent of the Biblical names of gems is uncertain in the nomenclature of modern mineralogy, and as a consequence there are several distinct lists of names given for the stones in the breastplate. In the Section of Comparative Religions in the United States National Museum is a very old silver breastplate employed as an ornament for the manuscript copy of the Torah, or Pentateuch, used in an ancient synagogue. The twelve stones, with the names of the

¹ Report of the U. S. National Museum, 1896, p. 913. A collection of these stones is on exhibition in the division of Old World Archaeology, Department of Anthropology.

twelve tribes, according to it are as follows: Garnet, Levi; diamond, Zebulon; amethyst, Gad; jasper, Benjamin; chrysolite, Simeon; sapphire, Issachar; agate, Naphthali; onyx, Joseph; sard, Reuben; emerald, Judah; topaz, Dan; beryl, Asher.

The second list is that given in the description of the ornaments of the Prince of Tyre (Ezekiel xxviii, 13):

1. <i>Odem.</i>	2. <i>Pitdah.</i>	3. <i>Yahalom.</i>
4. <i>Turshish.</i>	5. <i>Shoham.</i>	6. <i>Yashpeh.</i>
7. <i>Sappir.</i>	8. <i>Nofek.</i>	9. <i>Bareketh.</i>

The third list is that given in the description of the Heavenly City (Revelations xxi, 19, 20). As in the preceding list, the word used in the original, or Greek, is followed by the rendering given by most authorities, that of the Revised Version in parentheses:

1. <i>Iaspis</i> , jasper.	2. <i>Sappeiros</i> , sapphire or lapis lazuli.	3. <i>Chalkedon</i> , chalcedony.
4. <i>Smaragdus</i> , smaragd (emerald).	5. <i>Sardonyx</i> , sardonyx.	6. <i>Sardios</i> , sardius.
7. <i>Chrysolithos</i> , chrysolite.	8. <i>Beryllos</i> , beryl.	9. <i>Topazion</i> , topaz.
10. <i>Chrysoprasos</i> , chryso-prase.	11. <i>Hyakinthos</i> , jacinth (sapphire).	12. <i>Amethystos</i> , amethyst.

In addition to the gems enumerated in these lists, there is mentioned the diamond by the Hebrew name of *shamir* (Jeremiah xvii, 1; Ezekiel iii, 9; Zechariah vii, 12); amber, Hebrew *Hashmal* (margin of Revised Version gives *electrum*) (Ezekiel i, 4); and crystal (quartz), Hebrew *qerah* and *gabish* (Ezekiel i, 22; Job xxviii, 18; Revelation iv, 6).

The complete list of gems mentioned being as follows:

Agate, Hebrew *shebo*.—One of the stones in the breastplate of judgment. (Exodus xxviii, 19.)

Amber, Hebrew *hashmal*.—Ezekiel i, 4. Some render the Hebrew *leshem* as amber, thus making it one of the gems in the breastplate. (Exodus xxvii, 19.)

Amethyst, Hebrew *ahlamah*.—One of the stones in the breastplate. (Exodus xxviii, 19.) In Revelation xxi, 20, it is mentioned as garnishing the twelfth foundation of the heavenly Jerusalem.

Beryl, Hebrew *shoham*.—One of the stones in the breastplate. (Exodus xxviii, 20.) Mentioned as one of the ornaments of the King of Tyre. (Ezekiel xxviii, 13.) In Revelation it is spoken of as adorning the eighth foundation of the Holy City.

Caruncle, Hebrew *nofek*.—One of the stones in the breastplate. (Exodus xxviii, 18; see also Ezekiel xxviii, 13.) The word *nofek* has been rendered ruby.

Carnelian, perhaps the Hebrew *odem* of the breastplate (Exodus xxviii, 17), and the sardius in Revelation xxi, 20. In Revelation iv, 3, of the Revised Version, is the rendering sardius. In the Authorized Version the reading is: "And he that sat was to look upon like a jasper and a sardine stone." In the Vulgate: "Et qui sedebat similis erat aspectui lapidis jaspidis et sardinis." The Textus receptus (Greek) is: *Και ὁ καθήμενος ἦν ὁμοιος ὀράσει λίθῳ ἰασπίδι; καὶ σαρδίνιῳ.* All other editions have for

the last word, *σαρδίω*. It is evident that the Vulgate and the Authorized Version simply followed the *Textus receptus*, and that the correct rendering is "sardius" and not "sardine stone."

Chalcedony.—The Hebrew *tarshish* (Exodus xxviii, 20) has been rendered chalcedony. In Revelation xxi, 19, it is enumerated in the description of the foundation of the New Jerusalem.

Chrysolite.—(See Revelation xxi, 20.) The Hebrew *tarshish* (Exodus xxviii, 20) has been rendered chrysolite.

Chrysoptase.—One of the stones in the foundation of the Heavenly City. (Revelation xxi, 20.)

Diamond, Hebrew *shamir*.—(See Jeremiah xvii, 1; Ezekiel iii, 9; and Zechariah vii, 12, where it is spoken of as an object of extreme hardness. In the Authorized Version the Hebrew *yahalom* (Exodus xxviii, 18) is rendered diamond.

Emerald, Hebrew *barcketh*.—One of the stones in the breastplate. (Also see Revelation iv, 3.)

Jacinth, Hebrew *leshem*.—A stone in the breastplate. (Exodus xxviii, 19.) The eleventh foundation of the Heavenly Jerusalem. (Revelation xxi, 20.)

Jasper, Hebrew *yashpeh*.—A stone in the breastplate. (Exodus xxviii, 20.) Mentioned as adorning the Prince of Tyrus (Ezekiel xxviii, 13.) One of the stones enumerated in the description of the Heavenly City. (Revelation xxi, 19.)

Onyx, Hebrew *shoham*.—One of the stones in the breastplate. (Exodus xxviii, 20; see also Genesis, ii, 12; and Ezekiel xxviii, 13.) According to certain renderings the *shoham* is beryl. *Shohams* set in gold were put on each of the two shoulder straps of the *ephod* of the high priest, and the two were engraved with the names of the twelve tribes, six on each. (Exodus xxviii, 12.)

Pearl.—It is thought that pearl is meant by the Hebrew *peninim*, a word often employed in the Old Testament as a figure of something valuable and precious. (See Proverbs, iii, 5; xxxi, 10, and Job xxviii 18.) Jesus uses the pearl for the same purpose in Matthew vii, 6, and xiii, 45.

Ruby, Hebrew *nofek* or *odem*.—One of the gems in the breastplate. (Exodus xxviii, 17; see also Ezekiel xxvii, 13.)

Sapphire, Hebrew *sappir*.—One of the stones in the breastplate. (Exodus xxviii, 18; also mentioned in Ezekiel xxviii, 13, and Revelation xxi, 19.) Some authorities render *sappir* as lapis lazuli, and not sapphire.

Sardonyx, Hebrew *yahalom*.—One of the stones in the breastplate. (Exodus xxviii, 18.)

Topaz, Hebrew *pitdah*.—One of the stones in the breastplate. (Exodus xxviii, 17; also mentioned in Ezekiel xxviii, 13, and in Revelation, xxi, 20.)

APPENDIX 3.

MYSTICAL PROPERTIES OF GEMS.

Man has endowed gems with talismanic, curative, and supernatural powers. Certain gems preserved him from incubi, vampires, and kindred terrors; others preserved him from the powers of sorcery or conferred the powers of witchcraft; by their aid he controlled the spirits of evil or was protected from their malign influence. With a suitable gem he could foretell the future, review the past, or conjure up pictures of events taking place at a distance. Protected by their mystic influences he feared neither plague nor poison, while his belief in the marvelous efficacy of their curative powers gave them a place among his most potent remedies.

The virtues of gems were diverse. Some procured the favor of the great; others rendered their possessors amiable, wise, strong, and brave; some protected him from fire, lightning, and tempests; others from danger and disease: some were preferred as talismans and charms; others were used as drugs, either alone or with electuaries, and with or without prayers, incantations, or other prescribed formulas.

Certain gems brought good or evil through the planetary influence of certain days. All yellow gems were appropriate for Sunday wear through the name giver, the sun. On Monday, the moon day, all white stones except the diamond were to be worn. Tuesday, the day of Mars, claimed garnets, rubies, and all red stones. Wednesday demanded blue stones. Thor's day, or Thursday, required amethysts and other stones of a sanguine tint. Friday, the day of Venus, had for its gem the emerald. Saturn's day claimed the diamond.

A particular stone was potent for good during a particular month, and, under the proper astrological control was supposed to have a mystical influence over the twelve parts of the human anatomy. Such a gem was the more potent if the natal day of the wearer corresponded with its particular sign, and when worn as a birth or month stone was supposed to attract at all times propitious influences and avert malign effects. The more important stones, their zodiacal control, and most potent periods of influence are:

Stone.	Zodiacal control.	Period.
Garnet.....	Aquarius.....	Jan. 21 to Feb. 21.
Amethyst.....	Pisces.....	Feb. 21 to Mar. 21.
Bloodstone.....	Aries.....	Mar. 21 to Apr. 20.
Sapphire.....	Taurus.....	Apr. 20 to May 21.
Agate.....	Gemini.....	May 21 to June 21.
Emerald.....	Cancer.....	June 21 to July 22.
Onyx.....	Leo.....	July 22 to Aug. 22.
Carnelian.....	Virgo.....	Aug. 22 to Sept. 22.
Chrysolite.....	Libra.....	Sept. 22 to Oct. 23.
Aquamarine.....	Scorpio.....	Oct. 23 to Nov. 21.
Topaz.....	Sagittarius.....	Nov. 21 to Dec. 21.
Ruby.....	Capricorn.....	Dec. 21 to Jan. 21.

A closely related idea is found in the 12 stones which, according to the Jewish cabalists, when engraved each with an anagram of the name of God, were supposed to have a mystical power over, and a prophetic relation to, the 12 angels. Thus:

Ruby.....	Malchediel.
Topaz.....	Asmodel.
Carbuncle.....	Ambriel.
Emerald.....	Muriel.
Sapphire.....	Herchel.
Diamond.....	Humatiel.
Jacinth.....	Zuriel.
Agate.....	Barbiel.
Amethyst.....	Adnachiell.
Beryl.....	Humiel.
Onyx.....	Gabriel.
Jasper.....	Barchiel.

These stones also had reference to the Twelve Tribes of Israel, the 12 parts of the human body, 12 hierarchies of devils, etc. By their aid a system of prognostication was practiced, based upon the change of hue or brilliancy of the stone, so that the cabalist was enabled to foretell future events.

The Twelve Apostles were represented symbolically by precious stones: Jasper, St. Peter; sapphire, St. Andrew; chalcedony, St. James; emerald, St. John; sardonyx, St. Philip; carnelian, St. Matthew; beryl, St. Thomas; chrysoprase, St. Thaddeus; topaz, St. James the Less; hyacinth, St. Simeon; amethyst, St. Matthias.

The superstitions connected with the 12 stones have persisted in one form or another from the times of the Magi to the present, and the belief in their virtues can still be traced in the wearing of "birth-stones," as listed below:

BIRTH STONES.

January....	Garnet (also hyacinth).
February...	Amethyst (hyacinth and pearl occasionally used).
March.....	Bloodstone (also jasper).
April.....	Diamond (also sapphire).
May.....	Emerald (chalcedony, carnelian, and agate occasionally used).
June.....	Agate (chalcedony, turquoise, pearl, and cat's-eye occasionally used).
July.....	Ruby (carnelian, onyx, sardonyx, and turquoise occasionally used).
August....	Sardonyx (carnelian, moonstone, alexandrite, and topaz occasionally used).
September..	Sapphire (also chrysolite and sardonyx).
October....	Opal (also beryl and aquamarine).
November..	Topaz (also pearl).
December..	Turquoise (ruby, bloodstone, and chrysoprase occasionally used).

In the *Sympathia Septem Metallorum ac Septem Selectorum Lapidum ad Planetas* is a list of stones recorded as being in sympathy with the planets, and as such were possessed of astrological and medic-

inal properties which, under the proper sign, rendered them of service to men. Thus—

[♄]	Saturn.....	Turquoise, sapphire.
[♃]	Jupiter....	Carnelian, topaz, amethyst.
[♂]	Mars.....	Jasper, emerald.
[♀]	Venus.....	Emerald, amethyst, topaz.
[☿]	Mercury...	Crystal, agate, emerald.
[♁]	Moon.....	Moonstone, topaz, and all white stones.
[♁]	Sun.....	Diamond, ruby.

The Hindu propitiated hostile stars by the bestowal of gems. If the sun was hostile, a pure ruby; the moon, a good pearl; if *sani*, a star affecting to a powerful degree the destinies of men, a sapphire. He also averted the evil effects of adverse astral influences by wearing certain stones. If the sun was adverse, the cat's-eye; if the moon, the sapphire, etc.

The mystic ascribed a certain significance both to the gem and to its various colors. For example, white was the emblem of light, purity, faith, innocence, joy, and life; worn by women it was emblematic of chastity; by the ruler, of humility and integrity. Red signified pure love and wisdom; in other sense it signified passion, love of evil, hatred, etc. Blue was indicative of truth, constancy, and fidelity. Yellow in one sense was symbolical of marriage and faithfulness; in another sense of inconstancy, jealousy, and deceit. Green was the color of hope, especially that of immortality. Amethystine signified love, truth, passion, suffering, and hopefulness, and among the Rosicrucians was symbolical of the divine male sacrifice.

Stones of all sorts were engraved with the figure of a cockatrice, which, under the proper planetary influence, were preservatives against the evil eye. The names of Jesus, Mary, and Joseph were engraved on stones, chiefly amethyst, onyx, and bloodstone, which were worn as preventives of contagious diseases; the larger the stone, the greater its efficacy. Gems were also supposed to indicate the state of health of the donor or wearer. If the stone became dull, opaque, or colorless it was thought to be significant of danger and death. In a similar manner they lost or changed color in contact with poisons.

Dreaming of gems was usually fraught with good, while seeing or handling them on the eve of a journey, or at certain phases of the moon, was regarded as auspicious.

Supernatural influences have been attributed to gems which still pass current. For example, an onyx ring, supposed to be the espousal ring of Mary and Joseph, exhibited in the Duomo of Perugia, is thought to be efficacious in the cure of every disorder. Amber is still used as a prophylactic and curative for goiter, croup, and diseases of the throat. The opal is thought by many to bring ill luck to the

wearer. The coral is still believed to be a charm against diseases of childhood, and is extensively worn in Italy as a protection against the "evil eye." Pearls are dreaded by some and favored by others. No French bride will wear them on her wedding day, since they would bring tears to her married life. In the East the believers are dogmatic in their faith, and it is heresy to assert that the use of gems has no practical influence over body or mind.

It is impossible here to do more than hint at the many beliefs concerning gems which were or are current, and the following notes merely suggest a few of the more prevalent beliefs on this subject:

Agate.—Emblematic of health and wealth. An enemy to all venomous things; assuages thirst when held in the mouth; gives victory to its wearer; repels storms; sharpens the sight; preserves and increases strength, and renders its wearer gracious and eloquent. (Camillus Leonardus, *Speculum Lapidum*, 1502.) Efficacious as an amulet against scrofula and skin diseases. (Albertus Magnus, *De Vertutibus Herbarium, Lapidum, Animalum, etc.*) Various properties are attributed to it by Mohammedan authorities. It cured insanity when administered with water or with the juice of the fruit *Sheu* (an apple?); a remedy for hemorrhage in the genital organs or in the rectum; for the spitting of blood; for the unusual discharge of the menstrual fluid. In conjunction with other medicines it cured hard boils and porous ulcers, gravel, spleen, and kidney troubles. It prevented bleeding of the gums and rendered them hard when applied to the parts as a calcined powder.

Agates having the reddishness of the water after washing raw flesh in the shape of finger rings prevent bleeding of all kinds. The wearer strikes terror to the heart of his enemies, obtains his heart's wishes from the gods, and becomes free from pain in the breast.

The *Akik* (agate) confers upon the wearer all the blessings that the use of the turquoise does. Its internal use may do harm to the stomach, but this can be avoided by mixing it with *Katira*, or, in its absence, with the *Basud* stone. (Views of Arabic and Persian writers on gems and stones.)

If taken internally, the agate drives away fear, increases the power of digestion, cures insanity and monomania of that kind which creates the impression of being beaten and abused by others. If worn, it cures stricture and the vomiting of blood coming from the chest; worn on the neck, it cures the spitting of blood issuing from the lungs at the time of coughing. Calcined, powdered, and administered with white wine in doses weighing 16 barleycorns, it cured the gravel. If tied about the thighs of a woman under painful labor, it helps to a speedy and easy delivery. The weight of the stone here prescribed should be about 120 barleycorns. (Ben Adloulah.)

The eye-agate was considered efficacious as an amulet in cases of scrofula and other skin diseases. In great repute to-day in Syria as a curative for "Aleppo" sores.

Pierre de Boniface, writing in 1315, said:

The agate of India or Crete renders its possessor eloquent and prudent, amiable, and agreeable.

Ben Jonson, in the *Alchemist*, speaking of the medicinal properties of gems, wrote:

My meat shall come in Indian shells, dishes of agate set in gold, and studded with emeralds, sapphires, hyacinths, and rubies. The tongues of carps, dormice, and camel's heels boiled in the spirit of Sol, and dissolv'd pearl, apicus diet 'gainst the epilepsy. And I will eat these broths with spoons of amber, headed with diamond and carbuncle.

Dioscorides, in his *Materia Medica*, recommends the use of the agate as a preventive of contagion.

Alabaster.—According to Leonardus it is the best for vessels to hold unguents, which are preserved in them without spoiling. Dioscorides and many other doctors account it good in physics. He who carries it will prove victorious in suits at law.

Amber.—Supposed to be “generated out of the urine of the lynx, and is hardened by time; that voided by the male, brown; by the female, saffron, inclining to a darkness.” Amber assuaged pain in the stomach, cured jaundice, flux, and king's evil.

It naturally restrains the flux of the belly; is an efficacious remedy for all disorders in the throat (a belief still prevalent). It is good against poison. If laid on the breast of a wife when she is asleep, it makes her confess all her evil deeds. Being taken inwardly it provokes urine, brings down the menses, and facilitated a birth. It fastens teeth that are loosen'd, and by the smoke of it poisonous insects are driven away. (Camillus Leonardus, *Speculum Lapidum*. 1502.)

When buried in a moist soil it was supposed to generate a fungus, which was administered to those troubled with the gravel. It cured fits, dysentery, scrofula, and jaundice. Used as an amulet it charmed away toothache, asthma, croup, and diseases of the throat; supposed to be efficacious as a curative and prophylactic if rubbed on the parts or taken internally, after dissolving in white wine. (*Dissertatio medica de Succino*, 1682.) These beliefs are still current.

Thomas Nicols writes that the—

white odoriferous amber is esteemed the best for physic use, and thought to be of great power and force against many diseases, as against the *vertigo* and *asthmatic paroxysmes*, against *catharres* and *arthriticall* pains, against diseases of the stomach, and to free it from sluffings and putrefactions, and against diseases of the heart, against plagues, venoms, and contagions. It is used either in powder, or in oil, or in troches, either in distempers of men or of women, either married or unmarried, either with child or without, or in the distempers of children. (*Arcula Gemmea*, 1653.)

Olaus Worm, of Copenhagen, writing in 1640, says that amber was received as a panacea; a sovereign remedy for toothache, asthma, and dropsy.

In the work “*De Proprietatibus Rerum*,” by Bartholomaeus Glanvilla, amber is reported to possess the property of driving away adders and of being contrary to friends.

The Shah of Persia is said to wear an amulet of amber reported to have fallen from heaven, and which has the property of rendering him invulnerable.

Amber is used to-day in Lombardy and the Piedmont as a cure for goiter—a belief that dates back to the time of Pliny.

Amethyst.—Emblematic of sincerity.

As an amulet it dispelled sleep, sharpened the intellect, prevented intoxication, gave victory to soldiers, and protected its wearer from sorcery. (Leonardus.)

“The amethyst banishes the desire for drink and promotes chastity.” (Art Magic; or Mundane, Submundane, and Supermundane Spiritism.)

Lost its color in contact with and was an antidote for all poisons. (Albertus Magnus.)

According to Pliny, the amethyst was an antidote to drunkenness, and it takes its name from this property. Moreover, if the name of the moon or sun be engraved on it and it be thus hung about the neck from the hair of a baboon or the feathers of a swallow, it is a charm against witchcraft. It is also serviceable to persons having petitions to make to princes. With the assistance of a spell or incantation it kept off hailstorms and flights of locusts.

Porta, in his treatise on magic, says that the amethyst neutralizes magic incantations.

The Puranas hold that the amethyst “gives strength and cures morbid heat and fistula.”

Beryl.—Used with incantations to foretell the future and review the past, was efficacious in detecting thieves, forewarned death, and was supposed to have power over and to be the abode of evil spirits that could be made to work the wearer's will by means of suitable incantations. It rendered its owner cheerful, preserved and increased conjugal love, cured diseases of the throat and jaws and disorders “proceeding” from the humidity of the head, and is a preservative against them.” (Camillus Leonardus, *Speculum Lapidum*. 1502.)

According to Freeman, who wrote in 1701—

The beryl disturbs devils beyond all others. If it be thrown in water with the words of its charm sung it shews various images of devils and gives answers to those that question it. Being held in the mouth, a man may call a devil out of hell and receive satisfaction to such questions as he may ask.

Browning, in one of his poems, makes use of this belief.

The beryl was largely used for divination in 1600. The method was as follows: A bowl was filled with water and the ring suspended in it. The answer to the question propounded was spelled out by the ring striking the sides of the vessel. A modification of this, and one still in use, was to mark the edges of the bowl with the letters of the alphabet; the stopping of the ring at certain letters composed the answer. Still another method, and one said to have been used by Napier, was to throw a sphere cut from the stone into a bowl of water.

The character of the circles formed announced whether the presiding demon was favorable or not. If favorable, the information desired was pictured on the surface of the bowl.

Prior to the seventeenth century the beryl was in some repute as a curative. Mixed with an equal weight of silver, its powder, taken internally, was thought to cure leprosy. Water in which the stone had stood was good for the eyes, and, taken internally, it dispelled flatulency and cured indisposition of the liver.

Nicols, in the "Arcula Gemmea," published in 1653, said:

Wurtzung, in his general practice, saith that the beryll is used in all distempers of the heart. But take this caution by the way: Beware of the use of gemms (unless you are sure they be true) in physick, by reason they are so frequently adulterated.

Bloodstone.—Symbolical of wisdom, firmness, and courage.

Used with the proper incantations, its owner was enabled to foretell the future, and if rubbed with the juice of the heliotrope, it rendered its wearer invisible. The stone brought safety and long life to its possessor, stopped the flow of blood, and was an antidote for poisons. (Camillus Leonardus, *Speculum Lapidum*. 1502.)

Albertus Magnus taught that it cured dyspepsia, strengthened the stomach, and, if "washed according to medicinal art," was a styptic. Mixed with honey or the white of an egg, its powder was held by him to be an excellent remedy for hard tumors, while its dust would cure proud flesh and running sores.

Pliny and Leonardus mention that if placed in a basin of water containing the juice of the heliotrope and set in the sun, the water will appear red and the sun bloody. After a time the water will apparently boil and overflow the basin. Taken out of the water, the sun and solar eclipses could then be viewed in the water as in a mirror.

In a "Booke of the Things that are brought from the West Indies," published in 1574, the statement is made:

They doo bring from the New Spain a stone of great virtue, called the stone of the blood. The Bloodstone is a kind of jasper of divers colours, somewhat dark, full of sprinkles like to blood, being of colour red, of the which stones the Indians dooth make certayne Hartes, both great and small. The use thereof both there and here is for all fluxe of bloode, and of wounds. The stone must be wet in cold water, and the sick man must take him in his right hand and from time to time wet him in cold water. And as touching the Indians, they have it for certayne that touching the same stone in some part where the blood runneth, that it doth restrain.

The bishop of Rennes, in the eleventh century, writing on the talismanic efficacy of stones, asserts that the bloodstone endows its bearer with the gift of prophecy and renders him proof against poison.

During the Middle Ages the belief was prevalent in Europe that the stone had its origin in a dark-green jasper which happened to lie at the foot of the cross at the time of the crucifixion, and upon which the blood of Christ fell, hence the red spots.

Carnelian.—According to Epiphanius it cured tumors and all wounds made by iron.

It preserved the strength, prevented hoarseness, and cleared the voice. (Camillus Leonardus.)

It cheered the soul, banished fear and enchantments, and preserved harmony. (Albertus Magnus.)

According to the work by Giov. B. Porta, the wearing of a carnelian insured victory in all contests save those of love.

As an amulet and as a powder it was supposed to be a sovereign remedy for hemorrhage. De Laet, in 1647, has described from a personal experience its power in stopping bleeding at the nose, and advises the wearing of rings cut entirely from the stone for this purpose. The belief in its efficacy in such cases still persists.

Cat's-eye.—The cat's-eye cheers the mind, cures pallor, brings on a safe delivery in case of protracted labor, especially if tied in the hair of a patient. Applied locally, it causes infants suffering from the croup to bring up phlegm.

Applied as an ointment to the eyes, it cures lachryma. Calcined, the powder applied to sores heals them, and will cause new flesh to appear in the place of proud flesh. (Ben Adoula.)

According to the Mani-Málá, "the cat's-eye is warm, sour, and curative of cold, chronic derangements of the spleen, and colic, and is generally auspicious when worn." The same authority says that the perfect cat's-eyes, which are "heavy, deliciously cool, flawless, smooth, and otherwise faultless," are considered very lucky; while those that are defective bring about loss of friends, ruin, and wasting of the body.

The Hindus group the cat's-eye in four castes, according to their quality, all of which are replete with lucky signs.

The Persians held that the stone ground to a fine powder, mixed with water and then dried in the sun, and the operation repeated until the powder soaks up four times as much water as was first put in, would cure dropsy and inflammation of the navel if applied locally.

The Assyrians dedicated the stone to the god *Belus*, and ornaments containing it would, after the proper religious ceremony, render its wearer invisible to his enemies.

Chalcedony.—Prevented and cured melancholy. Worn as an amulet and in contact with the hairs of an ass, it was a preventive of danger during tempests and sinister events. (Camillus Leonardus, *Speculum Lapidum*. 1502.)

Reported to drive away evil spirits, a preventive of melancholy and sadness, and would bring victory to its wearer. (Andrea Baccius, *Arnot. Super. 6, c. de Natur. gem.*)

Chrysoberyl.—As an amulet it dispelled evil dreams, fear, and melancholy; in addition, it possessed the properties of the beryl. (The Mirror of Stones. 1750.)

The oriental chrysolite (chrysoberyl) dispelled pestilential vapors and infectious airs. Taken internally, it alleviated asthma. (Rulandus, *Medicina Practica*. 1564.)

It was said to cool boiling water when immersed in it, soften anger, lose its luster on contact with poison, and induce its wearer to repent of the faults he had committed. (*Porta, Magiæ Naturalis*. 1561.)

According to the Mani-Málá, the chrysoberyl, when set in gold and worn about the neck or hand, removes disease and vicious habits, and increases family, life, and happiness.

Chrysolite.—Cardanus, in his "De subtilitate," says that he cured one C. Palavicinus of a fever and another person of the "falling sickness" by the administration of powdered chrysolite with wine.

The powder was prescribed as a remedy for asthma. Held under the tongue, it assuaged thirst in fever. (*Arcula Gemmea*. 1653.)

Chrysoprase.—Preserved the sight, banished covetousness, and rendered its wearer cheerful. (*Mirror of Stones*. 1750.)

Worn as an amulet, it assuaged the pains of gout. (*Arcula Gemmea*. 1653.)

Bound around the arm, it was supposed to become a diuretic, to expel gravel, and prevent the generation of the stone. (Rulandus, *Medicina Practica*. 1564.)

Citrini.—The citrini (yellow corundum) protected the wearer from danger while traveling, secured him from pestilential vapors, and procured him every courtesy. (*Arcula Gemmea*. 1653.)

Coral.—In the "*Arcula Gemmea*" is a rather interesting account of the coral, as follows:

This is a but of maratime beauty, and the delight of children, the best of nature's buds, as somewhat furthering the springtide of their growth. The corall is a plant of nature's setting in the sea, which, though being covered with the waters of the sea, it bee green and soft, yet so soon as it is elevated above the waves and discovered in the region of the aire it altereth its colour and changeth its nature; its colour from green to a very noble and beautiful red; its softnesse into the compacted firmness and solidnesse of a stone, beautifull and lasting; by the operation of the aire encompassing its sometimes soft and flaccid substance. It is (under the waters of a brinish sea) a thriving, growing plant, sprung by nature with the ornament of many pretty branches, which is no sooner violently forc'd from the place of its growth and brought to light above the overflowing of the waters, but it blushes at the injurious hand that offereth violence to its secret, silent, tender, spreading growth.

Ovid, the Roman poet, accounts for the origin of the coral in the "*Metamorphoses*" in the following manner:

Perseus, having cut off the head of the Medusa, placed it upon some twigs and leaves near the seashore. The twigs were turned to stone on contact with the head, were scattered far and wide beneath the sea by sea nymphs, and thus became the seeds of coral.

The coral was thought to be of greater beauty when worn by a man than by a woman. By its change of color it was thought to fore-

warn the approach of disease; and should the wearer become dangerously sick, the gem became spotted. Worn as an amulet, it drove away fear, kept men from the influence of sorcery and evil spirits. It was a protection against poison, plague, and storm. (*Arcula Gemmea*. 1653.)

It secured women from *incubus* and men *succubus* and hindered the delusions of the devil. (*Dioscorides, De Materia Medica*.)

Coral was administered, according to the following prescription, for vomiting, purging, and colic:

Tabellae Corallatae.

R. Corallorum rubeorum praeparatorum, ʒii; margaritar praeparator, ʒi; boli armeni, ʒβ; light aloe, ʒi. Sacch. albissimi dissoluti in aqua rosaru cinnamomi tenuioris quantum sufficit; fiat confectio in tabellis. (*Arcula Gemmea*. 1653.)

According to the "Medicina Practica" of Rulandus, written in 1564, a half drachm of powdered coral was given as a cardiac stimulant; and in all contagious diseases, fevers, and poisonings the "tinctura corallorum" and the "sal corallorum" were equally efficacious.

Stopped every flux of blood; drove away ghosts, illusions, and dreams; was a protection against lightning, wind, tempest, and attacks of wild beasts. (*Methrodorus*.)

It gave relief to pains in the stomach and heart and strengthened those organs. It made sound diseased gums, and cleansed putrid sores. The powder, taken with wine, was given for the gravel. If hung on fruit-bearing trees, it insured fertility and protected them from hail and blighting winds. A kind known as *Grogius* had the power of stopping thunder and lightning. (*Leonardus, Speculum Lapidum*. 1502.)

Before the time of Pliny coral was held in great esteem, but during his period it was apparently not so highly appreciated, since he remarks "that formerly it was deemed a most excellent antidote for poison." During the Middle Ages, however, it was in great repute throughout Europe both as a drug and as an amulet. It was at that time deemed a powerful astringent, and in demand as a talisman against witchcraft, poison, epilepsy, etc.

Boetius de Boot, writing in 1636, says that he was cured of a dangerous pestilential fever by taking 6 drops of tincture of coral. A. de Villeneuve prescribed 10 grains of coral for infants in order to preserve them from epilepsy or any other fit through life. It is still in repute as a preservative against children's diseases and is not infrequently worn suspended from the neck for this purpose. In India it is occasionally given to children in the hope of ridding them of the hives and kindred itches.

According to the Mani-Málá a deep red coral was worn as an immediate cure for poisoning. Kar, an oriental sage, says that any man who wears an ugly discolored and rough coral courts death.

Sanskrit medical science taught that coral is sour, sweet, a specific for cold and biliousness, nutritious, and grace imparting; and the wearing of it very beneficial to women.

According to the Arabic and Persian writers, as given by Tagore in his *Treatise on Gems*, a dose of coral was considered to be a good astringent, a remedy for all bleedings, and an antidote for all poisons. Worn over the parts it cured all stomach complaints; worn around the neck it stopped crying in infants and protected them from fear and sudden starts while asleep. In Afghanistan the coral mixed with gold dust is given as a tonic. In Egypt it is used according to the following receipt:

Cut open a lemon and put a piece of coral inside, cover the opening with a paste of clay, and place the whole under a fire for some time until it gets white from burning; remove it and after grinding the stone use it as an ointment for the eyes. Mixed with electuaries and taken internally it will give great physical strength.

Porta, in his *Magiae Naturalis*, says that the coral will arrest the flow of blood and keep off evil spirits. This belief still persists in Italy, where a hand holding a branch of coral is not infrequently worn as a protection against the evil eye.

Diamond.—This stone, being of all gems the purest, hardest, and most brilliant, was considered to be the most powerful in spiritual influences and was consecrated to all that was holy and heavenly. It was symbolical of constancy, purity, and innocence, and hence early used in betrothal rings. It softened anger, strengthened love, and was considered an infallible test of conjugal fidelity. To the ancients the diamond represented inexorable justice and unchangeable fate, hence the judges of Hades were described as having hearts and bosoms of adamant.

According to the Talmud, a certain gem, supposed to have been the diamond, worn in the girdle of the high priest, if brought in contact with an accused man became dark and dim if the suspect was guilty; if innocent the stone shown with increased brilliancy.

In Europe as late as 1700 the diamond was thought to be the most potent talisman against poison, pestilence, witchcraft, etc. It was esteemed a safeguard to virtue; was used as a preventive of and a cure for lunacy. It was supposed to drive away lemures, incubi, and kindred terrors; and was considered a preservative against lightning. The gem was supposed to possess sex, and Boetius de Boot mentions two such diamonds which by their union produced others and thus left a numerous progeny.

Sir John Mandeville also bears witness to the procreative powers of diamonds:

They grow together, male and female, and are nourished by the dew of heaven; and they engender commonly, and bring forth small children that multiply and grow

all the year. I have oftentimes tried the experiment, that if a man keep them with a little of the rock, and wet them with May dew often, they shall grow every year and the small will grow great.

Speaking further concerning the diamond, Mandeville held that in order to secure the greatest good from a diamond it should be worn on the left side:

For it is of greater virtue than on the right side; for the strength of their growing is toward the north, that is the left side of the world, and the left part of a man is when he turns his face toward the east. He who so carries the diamond upon him, it gives him hardness and manhood, and it keeps the limbs of his body whole. It gives him victory over his enemies, if his cause is just; and it keeps him that bears it in good wit; and it keeps him from strife and riot; from sorrows and enchantments; and from phantasies and illusions of wicked spirits. It makes a man stronger and firmer against his enemies; and heals him that is a lunatic, and those whom the fiend pursues or torments. And if venom or poison be brought in presence of the diamond, anon it begins to grow moist and sweat. Nevertheless, it happens often that the good diamond loses its virtue by sin, and for incontinence of him who bears it; and then it is needful to make it recover its virtue again, or else it is of little value.

Pierre de Boniface, a fourteenth century alchemist, taught that one of the virtues of the diamond was to render its wearer invisible and invincible.

In this connection the Shah of Persia is the possessor of a diamond set in a scimitar which is believed to render him invincible so long as he has it by him. The shah also has a five-pointed star of diamonds which is thought to make conspirators instantly confess their crimes when in its presence.

A diamond ring was given to Mary, Queen of Scots, by Ruthven, as a talisman against danger and poison. The queen also possessed two other diamonds—"one medicinable and against poison," the other "medicinable for the collicke."

According to the Puranas, the diamond varies in the preponderance of one or the other of the five primal elements—

Earth, water, sky, energy, and air. The "airy" sort gives heart and gracefulness, the "skyey" diamonds bring about the possession of all kinds of wealth. The ownership and use of those kinds in which energy predominates adds to puissance, heroism, and hope. Those diamonds which are white like the jessamine flower, white clouds, or the moon, and are possessed of six or eight corners, sharp ridged, that have originated from water, and that shine in the darkness, lead to the instant cure of snake bites, and prove efficacious in neutralizing the effects of other poisons, and prove a panacea as soon as worn.

Like men, diamonds are divided into castes—Brahmins, Vaisya, Kshatriyas, and Súdras. The wearing of superior Brahmin diamonds gives favor in the eyes of the gods. The better sort of the Kshatriya class bring about uniform success, accession of power, and destruction of foes. The best stones of the Vaisya class are productive of fame, wisdom, and skill in the fine arts. The higher order of the Súdra caste induce benevolence in their owner and make him hale and wealthy.

As the promiscuous intercourse of one caste with another gives rise to mixed castes among men, so it is with diamonds. These mixed castes give rise to impurities and flaws in the stones, and which, according to their nature and kind, are fraught with

grave trouble to man. Such diamonds cause unchastity; brings destruction; renders man apprehensive of snake bites; creates fear; leads to ruin, loss of family dignity, and death. Such stones are dangerous to pregnant women and contact with them may lead to abortion.

A shapeless diamond is fraught with danger; a dirty diamond with grief; a rough diamond with unhappiness, and a black diamond with various troubles. A three-cornered diamond gives rise to quarrels; a four-cornered diamond occasions various fears; a five-cornered one brings death; but a six-cornered stone is productive of good.

Since the use of impure diamonds leads to danger, causes swelling in wounds, faintness, leprosy, pleurisy, jaundice, etc., it is highly advisable to refine and purify the stone before using it medicinally.

The process is as follows: On some auspicious day dip the diamond in the juice of *Kantakari* (*solarium jaquiri*) and then burn it in a fire made of dried cow or buffalo dung. The burning should be carried on for a whole night. In the morning the diamond should be put under horse's urine and again burnt. These operations are continued for seven days. The stone is then immersed in a gruel made of various leguminous seeds to which assafoedita and rock salt have been added and heated repeatedly twenty and one times. By this means the diamond is purified and reduced to ashes. The taking of a diamond so treated gives longevity, strength, energy, beauty, develops the parts, and effects a cure for every distemper. (Mani-Málá.)

The Brahmin diamond is useful in chemical operations, and brings about the acquisition of power, friends, wealth, position, and good luck to one's family. A Kshatriya diamond wards off old age and premature death; a Vaisya one crowns every endeavor with success; while a Súdra one is a panacea.

The Hindu held that the diamond was masculine, feminine, or neuter according to its marking and appearance. The masculine kinds were considered the best and were useful in medicine. The feminine diamond was auspicious to women; but the neuter diamond was destructive of vigor and brought weakness and disappointment; as a medicine it was administered for impotency.

According to the views of Arabian and Persian authorities the diamond, if worn, imparted health and dispelled fear. Tied around the thighs of a woman about to be confined it brought on a safe and speedy delivery and assuaged the pain of labor. Cut into a hexagon and worn on the arm it cured epilepsy. Combined with other ingredients and used as a dentifrice it rendered the teeth bright and hard; its use in this manner was attended with risks, for on too long a contact with the teeth it caused them to fall out; while the presence of a single particle in the stomach was liable to produce death. It was a fatal poison if taken internally without electuaries; and—

if by accident one takes a quantity of it his life should not be considered safe until he is made to vomit it out by means of drinking a quantity of fresh cow's milk or some heated clarified butter, or by any other means, such as applying the fingers to the inside of the throat. The soup of some fatty flesh is then to be given to the patient to complete the recovery. (Tagore, Treatise on Gems.)

The Burmese call the diamond and arsenic by the same name, *chein*, on the ground that they are both fatal poisons.

This idea was not unknown in Europe, for we find the diamond listed as one of the poisons given to Sir Thomas Overbury when a prisoner in the Tower; while Benvenuto Cellini, the famous goldsmith, writing about 1560, relates how his life was preserved by the roguery of an apothecary, who, being employed to pulverize a diamond intended to be mixed in a salad for Cellini with the intention of poisoning him, substituted a beryl as cheaper, thus saving the life of Cellini.

According to Sanskrit medicine the diamond combined all the six tastes, cured every disease, brought health and strength, and was very useful in chemical operations. (Mani-Málá.)

In Egypt the diamond, when set in gold, gives health and wealth to its wearer.

According to Porta, in his *Magiæ Naturalis*, the diamond contends against sleeplessness, enchantments, and turns away wrath.

Rabbi Benoni, a fourteenth century mystic, held that the diamond was capable of producing somnambulism, and when used as a talisman with lodestone and sapphire it would attract such powerful planetary influences as to render its wearer almost invincible.

In *Art Magic; or Mundane, Submundane, and Supermundane Spiritism*, it is stated that the diamond is the most powerful of all means to promote spiritual ecstasy.

Emerald.—Emblematic of happiness. As an amulet it was a preserver of chastity, and betrayed or punished its violation by flying into pieces or losing color. It preserved women in childbirth and eased the pains of labor; water in which the stone had stood hastened the afterbirth. (Leonardus.) Applied to the lips it stopped hemorrhage. When hung around the neck it prevented epileptic attacks. (Albertus Magnus.)

Dedicated to Mercury.

Much used by astrologers for the purpose of divination. (Cardanus, *De Lapidibus Preciosis*.)

Albertus Magnus cites the case of a certain King of Hungary who, while wearing an emerald, had knowledge of his wife, upon which the stone broke in three parts.

There is such an enmity betwixt it and illegitimate venery, or the uncleanness of the flesh, as that if it do but touch the skin of an adulterer it will break, and that it doth bridle the reins of lasciviousness and much temper it. (Arcula Gemmea.)

Avenzoar held that it was an antidote for poisons, and that 6 grains of its powder taken in water made an excellent cordial.

Mundella, a sixteenth century physician, calls attention to the purchase of a fine emerald by Franciscus Maria, Prince of Urbine, for use as a remedy in the treatment of a disorder with which he was troubled. (Arcula Gemmea.)

Ahmed Ben Abdalaziz, in his Treatise on Jewels, says that if a serpent fix his eyes on the luster of emeralds he immediately becomes blind. Thus Moore in "Lalla Rookh":

Blinded like serpents when they gaze
Upon the emerald's virgin blaze.

The Shah of Persia has a small easket of gold studded with emeralds, said to have been blessed by Mahomet, which has the property of rendering the royal wearer invisible so long as he remains celibate.

The San Greal was a chalice made from a single emerald, and which possessed the power of preserving chastity, prolonging life, curing wounds and disease, and other wonderful properties. The Holy Grail was used at the Last Supper, and in it were caught the last drops of the blood of Christ as he was taken from the cross. In the legends and poetry of the Middle Ages are many notices of the Greal—a subject revived by Tennyson.

The Romans used it to rest, strengthen, and preserve the eyes, a practice which persisted through the Middle Ages, during which period water in which the stone had stood was used as a specific for ophthalmia.

Boetius de Boot gives directions for its treatment for use as a drug as follows:

Pound the emerald in an iron mortar, sift the powder through the muslin, then cover it with *spiritos urinae*; the spirit must be distilled off, leaving the powder of a gray color, but which will communicate that of the emerald to the spirits of wine.

This taken internally was considered a powerful remedy for many diseases, such as dysentery, epilepsy, venomous bites, fevers, etc.

According to Sanskrit medicine—

The emerald is cool, good in poisoning, sweet, and purgative, helps digestion, cures biliousness, removes disrelish, is nutritious, and wards off spectral influences. (Tagore, Treatise on Gems.)

The Hindu authorities held that the perfect emerald was an infallible remedy for all cases of poisoning; cleansed men from sin, brought about success in war, and rendered successful the rites performed according to the Atharva-Veda. The defective emerald led to sickness, injury, loss of male children, and rendered one liable to bites. (Mani-Málá.)

The Persian and Arabian sages taught that, whether worn or taken as a medicine, the emerald—

bestows contentment of mind; quickens the pulse; gives nourishment to the soul, heart, brains, and stomach; cures epilepsy; removes all bodily pain; stops the vomiting and purging of blood; is an antidote to poison; allays unnatural thirst; and is a panacea for jaundice, liver troubles, stricture, gravel, and leprosy.

If administered in doses weighing 8 wheat corns to a patient suffering from poison, it neutralizes its action, provided it be taken soon enough. To prevent vomiting of blood, the dose of the emerald should be the weight of 4 barleycorns. The powder,

applied to the eyes, brings out all impurities therein and stops the flow of fluid substances. When set in a gold ring and worn on the forefinger or thumb it is prophylactic against cholera. The ashes of burnt emerald heals ulcers if applied locally.

According to the Rosicrucians, if at the time when Sol enters Libra an emerald be set in a gold ring of the same weight and worn on the finger, its wearer would attain his cherished object and could detect the presence of poisons by the sweating of the stone.

The possessor of an emerald would never become poor.

If a serpent looked at this stone, he was struck with blindness.

The Egyptians held that the best test for a genuine emerald was that a serpent immediately fell to licking it as soon as it came across it.

The Aztecs administered its powder as a remedy for venereal diseases.

Garnet.—Emblematic of constancy. Its virtue was to dispel "poisonous and infectious airs" (Leonardus). During the Middle Ages it was considered to possess the same marvelous and medicinal properties as the ruby, though to a less degree. It gave and preserved health, drove away vain thoughts, and reconciled differences between friends.

Suspended from the neck, it kept off plague and thunder, strengthened the heart, and increased riches and honors. (Giov. B. Porta, *Magiae Naturalis*. 1561.)

According to the Puranas—

A garnet which is colored like the conch, the lotus, the black bee, or the sun, and which is strung on a thread, is sound and auspicious, and heralds good fortune. A garnet which is colored like the crow, the horse, the ass, the jackal, the bull, or the blood-stained beak of a vulture holding a piece of flesh, brings on death.

Jacinth.—Procured sleep, riches, honor, and wisdom. A preservative against pestilence and foes. (Leonardus, *Speculum Lapidum*. 1502.)

Cardanus, in *De Lapidibus preciosis*, says that he was in the habit of carrying a jacinth about him for the purpose of inducing sleep, which he says "it did seem somewhat to confer, but not much."

Nicols, quoting Cardanus, says that jacinth procured sleep, cheered the heart, drove away plagues, brought protection from thunder, and increased wisdom and honor when worn on the finger or about the neck as an amulet. (*Arcula Gemmea*. 1653.)

Jade.—Worn as an amulet or administered internally, it was a curative of diseases of the kidney and loins.

Wecker, in the *Antidotae speciale de Lapidibus minus preciosis Alterantibus*, says that a nobleman, well known to him, had a fine "nephritick stone," which he wore on his arm—

by the power of which he voided a very great quantity of gravel, so great as that he feared lest he should suffer harm by so large an expulsion of it in so short a time.

Porta, in the *Magiæ Naturalis*, says: It alleviates the pain of the kidneys, expels gravels from the bladder, and when worn as a charm is a preservative against venomous things.

Jasper.—Was a charm against scorpions and spiders. (Boot, *Gemmarum et Lapidarum Historia*. 1690.)

Checked the flow of blood; strengthened the chest, lungs, and stomach; cured fevers and dropsy; cleared the sight, and prevented conception. (Leonardus, *Speculum Lapidum*. 1502.)

In the list of valuables left by George, Earl Marischal, who died in 1620, is "ane jasper stone for stemming of bluid."

Mottled jasper, suitably engraved, was believed to prevent its wearer from death by drowning and to render him free from injury while on the water. (Arcula Gemmea. 1653.)

Burton, in the *Anatomy of Melancholy*, says:

If hung about the neck, or taken in drink, it much resisteth sorrow.

Nonus, a physician of the Middle Ages, reported of it that it cured epilepsy.

Galen asserted that a green jasper, worn as an amulet suspended from the neck so that it was above the navel, would cure dyspepsia and strengthen the stomach.

Jet.—Cardanus (*De Subtilitate*, lib. 5) says:

The wearing of this stone doth secure men from nocturnal fears, from incubus or succubus, or the nightmare, and from evil spirits; and that being drunk will show whether a maid hath her virginity or no.

Believed to dissolve spells and enchantments.

If burned as incense, its smoke drives away devils and relieves the dropsical. (Boetius, *De Gagate*.)

Bruised in water and given to a gravid animal, it brings forward the fetus. Its powder cures epilepsy and fastens loose teeth. Mixed with the marrow of a stag and taken internally it cures snake bites. (*Speculum Lapidum*. 1502.)

Used as a perfume it prevented irregularity in female periods. (Wurtz, *Tab. gener. prac.*)

Lapis-lazuli.—Believed to cure melancholia. (*Speculum Lapidum*.) Dioscorides, in *De Materia Medica*, suggests its use as a cure for melancholy, and states that it is a good purgative.

Cardanus advises its use in pectoral diseases of children and in epilepsy. The dose to be 5 grains. (*De Subtilitate*.)

Boetius (*Tract. de Lapidibus et Gemmis*) states that it is a good purgative. Unwashed, it purges by vomiting; washed, it purges by stool. Used for this purpose to-day in India, Chile, and Peru.

A. Mussa Brassavolus (*Lib. de Med. purgant.*) used it as a purgative according to the following prescription:

℞ Lapidis lazuli præparati, ʒj. Camphoræ, anisi, cinnamomi, zinziberis, mastiches ana, gr. 6. Misce, cum succo salviæ vel diacatholico fiant pilulæ quinq.

Dosis est à ʒij ad ʒj, aut in pilulis, aut in pulvere, aut in jure, aut in aqua Boraginis, aut in conserva Boraginis, aut in vino cretico.

According to Sanskrit medical science lapis-lazuli is cooling and a curative of biliousness. (Mani-Málá.)

Lodestone.—Orpheus, in the Hymni et de Lapidibus, says:

It will confer strength, banish disease, and when worn constantly about the person ward off epidemics and plagues. Sitting before it and fixing the eyes earnestly upon it one has but to ask the gods for light on any subject, and the answer will come breathing out through the stone. The soul will hear it and the senses discover it clearly.

In great repute in Europe during the fifteenth, sixteenth, and seventeenth centuries for its numerous virtues as an amulet and drug. Carried about the person it cured cramp and gout; held in the hand during the hour of travail it shortened the time and eased the pains of labor. Bruised and taken internally with the juice of fennel it cured disorders of the spleen; applied as an ornament it prevented baldness. A dram of the stone mixed with the fat of a serpent and the juice of nettles caused insanity. The powder thrown over a household fire caused the inmates to flee in a panic, an artifice, according to the popular belief, made use of by thieves. (The Mirror of Stones. 1750.)

It is good against the headache, convulsions, and poisons; and that it causeth easy delivery, and procureth love 'twixt man and wife, and preserveth peace and concord amongst friends, and that it driveth away fears and increases wisdom. Galen and Dioscorides say it. (Arcula Gemmea. 1653.)

Lodestone is in repute to-day as a preventive and cure for cramps, colic, and rheumatism. Among the American negroes it is used as a voodoo stone, and is thought to be a love charm; to possess phallic properties; to increase the strength of the body, and to cure lumbago, rheumatism, and hernia.

Malachite.—Thought to increase the strength and growth of children and ward from them all dangers and infirmities. (Pliny, Nat. Hist.; Solinus, Polyhist., C. 36; Baccius de Nat. gem., C. 29.)

It strengthened the stomach; preserved children from hurt and convulsions. (Arcula Gemmea.)

Boetius states that 6 grains taken internally acts as an excellent purgative. It will cure "cardialgia" and colic. (Tract. de Lapidibus et Gemmis.)

Held to be a powerful local anaesthetic, for "being taken in drink or bruised in vinegar and applied to the members that are to be cut off and burnt, it makes them so insensible that they feel scarce any pain. (Speculum Lapidum.)

Moonstone.—According to Pliny, "the image of the moon contained therein daily waxes or wanes according to the period of the lunar motion."

During the period of the increase of the moon it was a potent love charm; during the period of decrease it enabled its wearer to foretell the future. Carried in the mouth it became an aid to the memory. As a powder and amulet it was prescribed in case of epilepsy. (Camillus Leonardus.) It is still used for this purpose among the Basques. (Crevecoeur.)

Onyx.—Its origin, according to the Greek legend, was due to Cupid cutting the nails of the sleeping Venus with his arrow; these falling into the Indus were changed to onyx.

The stone was thought to be a powerful aphrodisiac; to increase spittle in children; hasten a birth; give rise to nightmare, and stir up strife. Used as an eyestone "it enters of its own accord, and if it found anything within that is noxious, it drives it out and tempers the hurtful and contrary humors." (Camillus Leonardus, *Speculum Lapidum*. 1502.)

The belief in its causing nightmare and strife was widespread. This belief was explained by Beononi on the assumption that "in the onyx is a demon imprisoned in the stone who wakes only of a night, causing terror and disturbance to sleepers who wear it."

Among the Persians the onyx is to-day administered as a drug for the cure of epilepsy.

Opal.—Symbolical of hope.

The gem was in great repute as an eyestone, and was used in all diseases of the eye. It partook of all the virtues of those stones whose colors it showed. (Camillus Leonardus, *Speculum Lapidum*. 1502.)

It stimulated the heart; preserves from contagious and infectious airs; drives away dispondency; prevents fainting, heart disease, and malignant affections. (Giov. B. Porta, *Magiae Naturalis*. 1561.)

The opal was supposed to indicate the state of health of its wearer by change of color, losing its brilliancy if the wearer was ill, and the opposite.

The idea that the opal is unlucky is based on a Teutonic superstition, and is comparatively modern. Mention of its supposed evil qualities is made in a work entitled "Art Magic; Mundane, Submundane, and Supermundane Spiritism," in which the opal is credited with being fatal to love and sowing discord between giver and receiver.

Pearl.—Emblematic of purity, beauty, and nobility.

Pliny states that pearls were supposed to be generated by a celestial dew falling on the shellfish, which, in the early mornings of certain seasons, left the bottom of the sea to draw in the air containing the dew from which the pearls were derived, the size and quality of the pearl depending upon the size of the dewdrop and the purity of the air.

Cloudy weather spoiled the color, lightning stopped the growth, and thunder ruined the gem.

According to the ancient Hindu authorities pearls were held to originate in elephants, clouds, boars, conch shells, fishes, frogs, oysters, and bamboos. Of these the oysters were the most productive. The pearls were formed by raindrops falling into the open shell of the mollusk, the finest gems being found during the period when the sun rested on Arcturus, the fifteenth lunar asterism.

In the Orient the pearl was and is extensively used as a medicine for syncope, hemorrhage, stomach troubles, etc. In China large quantities of seed pearls are made into an electuary and taken to restore manly vigor and as a stimulant.

According to Sanskrit medical science the pearl is "sweet in taste, very cool, and a specific for eye diseases, cures poisoning and atrophy, and brings strength to weak limbs." (Mani-Málá.)

The Arabian and Persian sages held that the use of pearls was conducive to contentment of body and soul; cured insanity and all mental diseases; all diseases of the heart, stomach, and bowels; piles, stricture, and excessive and insufficient menstruation. It was an antidote for poison, stopped bleeding from cuts, and cured leprosy and skin diseases.

Rambam recommends the use of the burnt powder as an ointment in the treatment of ulcers and diseases of the eye, such as conjunctivitis, cataract, etc. The burnt powder taken internally cured vomiting of blood and purging.

According to Egyptian medicine, pearl powder taken with electuaries strengthened the body and added luster to the eyes.

The Hindu authorities recognized four shades as belonging to pearls—yellow, honey, white, and blue. The first brings wealth, the second fosters understanding, the third brings fame, and the fourth good luck. If defective, according to the kind and degree, the pearl brought on leprosy, loss of male issue, loss of fortune, disgrace, slothfulness, insanity, and death. (Mani-Málá.)

According to Art Magic; or Mundane, Submundane, and Supermundane Spiritism, the wearing of pearls brought one en rapport with spirits and promoted chastity.

In Bengal bracelets of pearl are worn by virgins to preserve their virtue.

In Europe as late as the seventeenth century decoctions containing pearls were thought to be powerful mental stimulants and a cure for insanity. A decoction of pearl powder and distilled water was one of the remedies given to the insane Charles, King of Spain.

Leonardus states that pearls boiled in meat would cure the quartan ague; powdered and taken with milk, they healed ulcers and cleared the voice; they comforted the heart, gave relief in cramps and colic,

cured epilepsy and dysentery; taken with sugar, they were of assistance in the cure of pestilential fevers, and that they rendered their wearers virtuous.

According to Nicols (*Arcula Gemmea*) pearls were—

good against synopes, and cardiacall passions, that they do comfort the spirits, stop the fluxes of blood, cure lenteries and diarrheas, and that they are good for the sight.

Prase.—Supposed to possess all the properties of the emerald, but to a less degree. Lost its color on contact with poison or venom, but recovered it again on being washed. Reported to be an excellent cordial and cardiac stimulant. Applied to the eyes, it strengthened the sight. (*Arcula Gemmea*. 1653.)

Benoni states that the powder mixed with the milk of a ewe that has had but one lamb will, if applied locally, cure the gout; taken internally, it was a deadly poison.

Quartz.—The powder mixed with wine was given for dysentery in the north of England during the twelfth century. A crystal held against the tongue assuaged thirst. (*Leonardus, Speculum Lapidum*.)

Applied locally to-day in the mountains of Georgia for faintness, headaches, and bleeding at the nose. Used in parts of Virginia to cure styces; the sty is rubbed with the crystal three times a day for three days. In northern New York a so-called "vital ore," consisting entirely of quartz sand, is sold as a veritable panacea, curing sore eyes, piles, carbuncles, indigestion, sore throat, giddiness, and blood poisoning.

In the Middle Ages the clear, transparent quartz was believed to betray the presence of poison, either by becoming opaque or breaking. The powder, mixed with wine, was given in dysentery; held in the mouth, it assuaged thirst, cured headaches and faintness; powdered and taken with wine and honey, it filled the breasts of nursing women with milk. (*Leonardus*.)

Orpheus recommended its use as a medicine for diseases of the kidneys.

Andrea Bacci, writing in 1605, says:

It is used either in powder, or the salt of it, or the oil of it, against all obstructions of the bowels, against gouts, swoonings, and all cephalic diseases.

A drachm of the powder taken with oil of sweet almonds cures those that have taken sublimate. (*Arcula Gemmea*. 1653.)

Quartz balls were and are used by mystics, astrologers, and diviners to forestall the future, review the past, and conjure up distant scenes. The famous "show-stone" of Doctor Dee, a sphere 3 inches in diameter, was made of quartz. It is interesting to note that while the modern mystic and the mystic of the Middle Ages differ somewhat in their methods, each has the same end in view, and each has produced witnesses to show that he attained that end.

The methods used to induce a vision as practiced by the mystic of the Middle Ages are as follows: The crystal, according to Scot, in his *Discovery of Witchcraft*, when "charged" with the name of St. Helen, written on the stone with olive oil while the operator faced the east, and held in the hands of an innocent child born in wedlock, would, upon the recital of a prayer to the saint, become an oracle and answer any question put to it.

In an eighteenth century manuscript is the following statement:

Take a christall stone or glasse, most clear, without a craise, and wrape about it a pece of harte's lether, saying, "In the name of the Holy Trinity, and of the hey Deity Amen." Then holde the cristalle in the beam where the ☉ is most bright, at the hottest of the day, and say there con(jurations) subscribed, and by and by you shall sie the spirit peradventer, appeiring himselfe.

The spirit is then to be "charged," upon which he will point out the whereabouts of stolen property; the location of buried treasure; give information concerning relatives, friends, or enemies, or such other information as may be desired.

According to Hindu authorities the quartz is cool and cooling, cures hemorrhage from the nose and mouth, and when worn removes baneful astral influences.

The crystal gives strength and cures biliousness, morbid heat, and fistula. A specific for consumption, leprosy, and poisoning. It may enter into medicines as a substitute for diamonds. (Mani-Málá.)

A good rock crystal is an infallible remedy in all cases of poisoning. Wild animals like the leopard, the elephant, the lion, and the tiger, can not approach this gem. It neutralizes snake, rat, and scorpion poisons, and the wearer need never fear drowning, fire, or a thief. A moss-colored, clouded, rough, yellow, dull, dirty, and discolored rock crystal the authorities shun from a distance. (Tagore, a Treatise on Gems.)

Ruby.—Emblematic of love.

A sovereign remedy and amulet against plague, poison, evil thoughts, nightmare, and diverted the mind from sadness and sensuality. (Leonardus, *Speculum Lapidum*.)

It forewarned the wearer of the approach of any misfortune by loss of color. In this connection Wolfgang Gabelchover gives his experience:

On December 5, 1600, as I was travelling from Stuttgard in company with my beloved wife, Catherine Adelmann, of pious memory, I observed most distinctly during the journey that a very fine ruby, her gift, which I wore set in a ring upon my finger, had lost almost all its splendid color, and had put on dullness in place of brilliancy and darkness in place of light; which blackness and opacity lasted not for one or two days only, but for several. * * * Whereupon I warned my wife that some grievous mishap was impending over either her or myself, as I foreboded from the change of color in my ruby. Nor was I wrong in my anticipation, inasmuch as within a few days she was taken with a fatal sickness that never left her till the day of her death. And truly, after her decease, its former brilliant color returned spontaneously to my ruby.

Arabian and Persian writers taught that the wearer of the ruby obtained peace of mind and strength of brain.

A *durm* dose of it, taken internally, cures epilepsy, insanity, cholera, and the spitting of blood; causes free circulation of blood throughout the system, and prevents uneasiness of mind. It cures all kinds of poisonings from snake bite or from administration of poison by enemies. It frees the atmosphere from the pollution engendered by cholera. It purifies the blood and brings back to its normal state the fatally quick action of the pulse. The wearer of the ruby in the form of a finger ring obtains from the deity all the desires of his heart and becomes proof against thunder stroke and cholera. Worn over the eyes or applied to them as an ointment it cures all complaints of the vision; over the mouth it takes away the bad smell of it, allays thirst, and gives constant satisfaction to the mind. It brings honor to the wearer. The dose for internal use is from 1 kirat (4 barleycorns) to 1 dang (16 barleycorns). (See the work Karabadin Kabir, as cited by Tagore in his Treatise on Gems.)

The ruby enters into the Chinese pharmacopoeia as an ingredient in the "five precious fragments," supposed to consist of ruby, topaz, emerald, sapphire, and hyacinth.

The Hindu writers held that those rubies—

which are flawless and of approved color are auspicious, produce health, wealth, wisdom, and happiness. If flawed or offcolored they bring humiliation, loss of friends, liability to wounds, loss of wealth, and lightning stroke; are fatal to domestic animals, and are inimical to life, wealth, and fame. The man who treasures a ruby furnished with every perfection, and which when cast in a quantity of milk a hundred times its bulk, makes the white mass one entire sheet of red, or sends out a red flame, is as meritorious as the celebration of the *Aswamedha jagna*.¹ Such a stone leads to wealth success, happiness, and long life. (Mani-Málá.)

Sapphire.—Emblematic of wisdom. If placed on the heart it bestows strength and energy. St. Jerome states that the sapphire procures royal favors, softens anger, frees people from enchantment, obtains release from captivity, and prevents evil and impure thoughts.

Because of its extreme coldness it was thought to preserve the chastity of its wearer, hence especially suited for ecclesiastical rings.

Worn in a ring or in any other manner it is able to quench concupiscence, and for this reason it is proper to be worn by the priesthood and by all persons vowed to perpetual chastity. It is said to grow dull if worn by an adulterous or lascivious person.

It rendered its wearer chaste, virtuous, pious, devout, wise, amiable, and pacific. It cured boils, carbuncles, and headaches, rested and refreshed the body, and gave a color to the cheeks. Taken with milk it cured cramps. (Leonardus, *Speculum Lapidum*. 1502.)

Soaked in vinegar its vinegar extract was administered in fevers; powdered and soaked in vinegar for one phase of the moon, it was given to insure continency and conjugal love. (Galen.)

¹ The Horse Sacrifice, a celebrated ceremony, the antiquity of which dates back to the Vedic period.

Placed on the heart it cured fever; on the forehead it stopped bleeding at the nose. The powder taken with milk was a remedy for fevers, plague, and poison. (Albertus Magnus.)

The powdered sapphire used as an ointment cured inflammation and irritation of the eyes; it was also thought to be able to draw out any foreign substance that might be present in them. (Canones Medicinæ.)

According to Giov. Porta the sapphire was of great service in necromancy and the magic arts, and a deadly enemy to all venomous reptiles and insects. (Magiæ Naturalis. 1561.)

The Hindus regarded the stone as unlucky and as a bringer of misfortune. Thus:

A sapphire, the surface of which wears a micalike sheen * * * brings about loss of wealth and life. That mark in a sapphire which at first sight looks like a rift, * * * renders one liable to bites. That sapphire which is parti-colored causes loss of family dignity. The sapphire which contains dirt produces a variety of skin diseases like itching. That which contains gritty fragments is destructive; that which is rough causes banishment. (Mani-Málá.)

The same authority says, however, "that sapphire which when placed in a pot of milk darkens it all through, increases wealth, and is conducive to fame and increase of family," while "a flawless, sterling sapphire brings its wearer strength, fame, and length of days," and "the man who wears a sapphire of spotless chastity finds favor with *Narayana*,¹ and acquires longevity, family dignity, fame, understanding, and wealth."

According to the Sanskrit medical science the sapphire is bitter, warm, and good in cold and biliousness, and when worn alleviates the rage of *Sani*.²

In Egypt the sapphire is taken with *majoom* (electuaries) to add strength to the body. (Tagore, Treatise on Gems.)

The Buddhists esteem the sapphire above all gems, claiming that it produced tranquillity of mind, and when worn by one wholly pure and devoted to God insures protection against disease, danger, and venomous reptiles.

The sapphire is of a cold and drie faculty, even as are most pretious stones; it is reported of it that it is good against feverish distempers, hence this old distick.

Corporis ardorem refrigerat interiorem
Sapphirus, & cypriæ languida vota facit.

The best of these are very comfortable to the eyes if they be often looked on. (Arcula Gemmea. 1653.)

It is reported of it that if it be worn by an adulterer, by loosing its splendor it will discover his adultery. (Cardanus, De Lapidibus preciosis.)

The sapphire is of so contrary a nature to poisons that if placed in a glass with a spider the insect will quickly die. (Arcula Gemmea. 1653.)

¹ The preserver of the Hindu Triad.

² One of the stars influencing the destinies of men.

St. Jerome wrote that the sapphire conciliates to its wearer the condescension of princes, quells his enemies, disperses sorcery, sets free the captive, and may even assuage the wrath of God.

In the inventory of the jewels of Charles V mention is made of a "bluestone with two clasps of gold, good for the gout."

In the church of Old St. Paul's, London, was a famous sapphire which was supposed to cure the infirmities of the eyes of all those thus afflicted who might resort to it.

The modern mystic holds it capable of attracting powerful planetary influences, and nearly equal to the diamond and quartz in inducing visions. (Art Magic; or Mundane, Submundane, and Supermundane Spiritism.)

The star sapphire was and is still reputed to be a potent love charm. The powder of this gem was taken as an aphrodisiac during the Middle Ages. Star sapphire as a powder was given for vertigo in the low countries as late as 1810.

Sard.—Said to possess sex.

The males shine brighter than the females; for the females are the fattest and glitter more obscurely. (Leonardus, Speculum Lapidum.)

The sard nullified the evil effects of the onyx when worn with it, sharpened the wit, gave cheerfulness, and prevented dysentery. (Albertus Magnus, Leonardus, and De Boot.)

Epiphanius, writing in 1565, says that the sard conferred upon its wearer a cheerful heart, courage, and presence, and protected him from witchcraft and noxious humors.

Baccius in his Annotations says that powdered sard taken in spirits stops the menses and prevents miscarriage.

Sardonyx.—Symbolical of conjugal bliss. It rendered its possessor virtuous, cheerful, and agreeable. (Leonardus, Speculum Lapidum. 1502.)

Spinel.—Reconciled differences between friends; gave health and strength to the body; cured disorders of the liver; restrained passion and fiery wrath; and was a preservative from lightning. (Leonardus.)

Powdered and taken with water Arnobis used it as a remedy for diseases of the eye. (Dissertatio Medica.)

Boetius held that the wearing of a balas ruby (spinel) restrained fury, wrath, and lust.

In the *Arcula Gemmea*, written in 1653, the author, Nicols, says:

Rulandus reporteth this of it: That if the four corners of a house, arbor, or vineyard be covered with this stone it will preserve it from lightning, tempests, and worms.

According to Arabian and Persian medicine, the wearing of the spinel gives contentment, prevents the spitting of blood, cures piles and all diseases caused by the increase of phlegm. The dose for

internal use is from 1 *kirat* (4 barleycorns) to 1 *dang* (16 barleycorns). Applied as an ointment to the eyes the stone adds to their luster.

According to an Arabic work, entitled "Azaabul beldan," as cited by Tagore:

The sea cows get spinel stones from the Kokaf Mountains and put them on the ground when they come grazing toward Ceylon. The stone gatherers, who remain concealed all about, then come out in stealthy steps, carefully throw lumps of clay over the stones left, and then retire. When after grazing these animals go back to the sea, disappointed at not finding the stones and fretting and fuming with rage, those people came back and took away the precious stones.

Staurolite.—In Brittany, France, a superstitious reverence is attached to the cruciform crystals of this stone, based on a belief that they fell from heaven.

In Virginia and the Carolinas the staurolite, locally known as fairy stone, is worn as a lucky charm and is believed to bring good fortune and ward off danger and disease.

Sunstone.—According to Sanskrit authorities—
the sunstone is warm, flawless, and good in cold and defective oxidation, and sacred; it is an *elixir vitae*, and is the delight of the Sun. (Mani-Málá.)

Topaz.—Symbolical of friendship.

It cooled boiling water on being immersed in it; became opaque on contact with poisons; restrained anger and desire; cured insanity; checked the flow of blood; cleansed hemorrhoids; and averted sudden death. (Camillus Leonardus, *Speculum Lapidum*.)

Benoni states that the topaz is favorable for all hemorrhages and imparts strength and good digestion. Powdered and taken in wine it cured asthma and insomnia. (*Dissertatio Medica*.)

Rubbed on a hone the topaz gave a milky juice in quantities, and yet lost none of its original weight. The juice was taken internally in cases of dropsy and certain poisonings. Used as an ointment it was in repute as a curative for diseases of the eye. (Epiphanius.)

Worn as an amulet, so says Porta, it drove away sadness and nightmare; strengthened the intellect and bestowed courage. Mounted in gold and hung around the neck it dispelled enchantments; worn on the left hand it preserved its wearer from sensuality.

In the *Honest Jeweller*, written in the seventeenth century, the statement is made that—

the virtue and strength of the topaz is said to increase and decrease with the moon, and consist in the fact that when thrown into boiling water it at once deprives it of its heat.

According to the Sanskrit authorities, the—

topaz is sour, cool, and curative of abnormal oxidation, gives an appetite, and brings fame and wisdom.

The Hindu sages held that the medicinal properties of the topaz were similar to those of the coral, and in addition it prevented and cured sterility. (Mani-Málá.)

Like the ruby, the topaz was supposed to possess the power of emitting light to a great degree. A topaz given by the wife of Theodoric, count of Holland, to Adelbert, gave out so brilliant a light in the chapel where it was kept that prayers could be read by it.

Turquoise.—Emblematic of success. Highly valued by all orientals and worn by them to insure health and success. Supposed to preserve the wearer from injury through accidents. In the presence of poisons the stone sweated profusely, a property thought to be characteristic of many of the noble gems. Its color paled as its owner sickened and was lost entirely on his death, to be recovered only on its becoming the property of a healthy person.

The turquoise, according to Arabian and Persian authorities, as cited in the *Mani-Málá*, cured all diseases of the head and heart. A sovereign remedy for hernia, swellings, flatulence, dyspepsia, insanity, and cancerous sores. Whether taken alone, mixed with honey or with other drugs, it cures epilepsy, spleen, and stricture. In cases of poisoning or snake bite it was given with wine. Aristotle advises a similar dose for the same purpose. Applied as an ointment to the eyes it increased their luster, restored the vision, and prevented the fall of fluids therefrom. Worn as an amulet the turquoise brought happiness, dispelled fear, and rendered its wearer safe from drowning, lightning stroke, and snake bite. Seen after looking at the moon on the first day after the new moon it brought good luck.

In Egypt cure of a cataract is believed to be effected by the local application of a turquoise set in a silver ring and dipped in water, the application being accompanied by the chanting of the name of God.

Variolite.—Supposed to be a preventive and cure for variola (small-pox). (Castellani, *History of Gems*.)

Water sapphire or iolite.—A woman possessing a ring set with this stone as a signet, and on which was cut one-half of a fish, a mirror, a branch, and a nude female, procured any desire.

Zircon.—Supposed to bring riches, honor, and wisdom; a charm against plague and evil spirits; and afforded its wearer protection against thunderbolts. (Europe During the Middle Ages.)

According to the *Mani-Málá*—

The wearing of a weighty, lustrous, white, cool, tender, very old, and transparent gameda (zircon) leads to prosperity. A light, discolored, exceedingly rough, delusion creating, and cool, yet dirty, gameda blights happiness and saps the foundations of energy.

The same treatise, speaking of its medicinal value, says:

The zircon is sour, heating, and curative of unhealthy oxidation; sharpens the appetite, helps digestion, and takes away sin.

In conclusion, it would be expected to find the belief in the marvelous and medicinal properties of gems prevalent during the age of faith, while during the age of reason and inquiry it seems somewhat

childish that they should still continue to exist. In India, the land of occultism, the mystics still pursue their researches after the occult virtues of precious stones. The modern Western spiritualist endeavors to discover and apply the occult knowledge of the East. He still believes in and teaches the virtues of gems, and is emphatic in his opinion that certain gems facilitate the rapport of a certain class of spirits with the wearers of those gems.

Swedenborg, the Swedish mystic, in his spirit revelations to L. A. Cahagnet, as cited in his *Magic Magnetique* (Paris, 1838), gives numerous categorical answers to questions asked by the medium concerning the spiritual and material powers of certain precious stones.

In Paris a school has been established which has for its object the study of the magnetic emanations, radiance, and crystals. In Nice a Doctor de Lignieres has issued a prospectus of a work of 644 pages that seriously considers the medicinal properties and virtues of precious stones.

APPENDIX 4.

GEM AND MINERAL NAMES.¹

The following list of gem names has been compiled from the literature and from correspondence with the producers of precious stones in the United States. The list is in two parts. Part I gives the name of the gem followed by the name of the mineral species to which the gem belongs. Part II aims to give all the names of the mineral species followed by the names of the corresponding gems.

Many of the names have been coined by the dealers in particular minerals for the evident purpose of increasing their sales. Many people who buy cheap gem stones under fanciful names probably would not buy the stones if they were offered under their true mineralogic names. The list herewith will enable those who are interested to look up the true mineral species of the gems offered.

The use of the name of a valuable gem mineral combined with another modifying word instead of the true name of a mineral of less value—for example, "Alaska diamond" instead of quartz, or "Arizona ruby" instead of garnet—is incorrect and should be avoided. The list does not contain all the names applied to gem minerals. Such self-evident names as "milky opal" and "blue beryl" are omitted. The object of the list is to show the mineral species forming the gem and not to list all possible names which have been used for gems.

A few names of substances not minerals but commonly used as gems have been included. Artificial products, however, many of them made of glass and fraudulently sold under mineral names—for example, glass sold as "fire agate"—have been excluded.

PART 1.—GEM NAMES.

A.

Achirite=diopside from Siberia.

Achroite=colorless or white tourmaline.

Actinolite=green iron, calcium, and magnesium silicate (amphibole).

Adamantine spar=hair-brown corundum.

Adelaide ruby=blood-red pyrope (garnet) from South Africa.

Adularia=orthoclase (feldspar).

Aeroides=pale sky-blue beryl.

Agalmatolite=compact mica (aluminum and potassium hydrous silicate); also compact pyrophyllite (aluminum hydrous silicate).

Agate=variegated chalcedony.

¹ From Mineral Resources of the United States for 1917, by Dr. W. T. Schaller, of the United States Geological Survey and formerly custodian of gems and precious stones in the United States National Museum.

- Agate jasper=intermediate between jasper and chalcedony with predominant translucent chalcedony; jasper with bands of chalcedony.
- Agrite=brown, mottled, calcareous stone.
- Alabandine ruby=red spinel of a violet tint.
- Alabaster=white, fine-grained gypsum; also incorrectly applied to fine-grained and pure-white stalagmites of aragonite.
- Alalite=diopside.
- Alaska diamond=quartz.
- Albite=aluminum and sodium silicate (feldspar).
- Albite moonstone=iridescent albite.
- Alençon diamond=quartz crystal from Alençon, France.
- Aleppo stone=eye agate.
- Alexandrite=emerald-green to dark-green chrysoberyl which changes in color to a columbine-red by artificial light.
- Allanite=black hydrous aluminum, magnesium, cerium, and iron silicate and other elements.
- Almandite (almandine)=columbine-red, or a deep crimson and violet garnet, aluminum and iron silicate.
- Almandine spinel=violet-red spinel.
- Alpine diamond=pyrite.
- Amatrice=green, blue-green, and bluish variscite cut with its associated matrix.
- Amazon stone=green microcline feldspar, aluminum and potassium silicate.
- Amber=fossil resin.
- Amber opal=opal colored brown by iron oxide.
- Amberine=yellowish-green agate from the Death Valley region, California.
- Ambroid=small pieces of inferior amber fused together.
- American jade=californite (vesuvianite).
- American ruby=blood-red garnet, mostly pyrope.
- Amethyste basaltine=pale violet or reddish beryl.
- Amethyst=purple and bluish-violet quartz, in crystals.
- Amethystine quartz=quartz of an amethyst color, not necessarily in crystals.
- Amphibole=group of minerals, aluminum, iron, calcium, magnesium silicates, and silicates of other elements.
- Anatase=titanium oxide. Another name for octahedrite.
- Ancona ruby=quartz.
- Andalusite=aluminum silicate; also trade name for brown tourmaline.
- Andesine=aluminum, sodium, and calcium silicate (feldspar).
- Andradite=garnet, iron and calcium silicate.
- Anthracite=hard iron-black coal, harder than jet or cannel coal.
- Apatite=calcium phosphate, with fluorine.
- Aphrizite=black tourmaline.
- Apophyllite=calcium and potassium hydrous silicate.
- Apricotine=yellowish-red quartz pebbles from vicinity of Cape May, New Jersey.
- Aquamarine=light bluish-green or sea-green beryl.
- Aquamarine chrysolite=greenish-yellow beryl.
- Aquamarine topaz=greenish topaz.
- Aragonite=calcium carbonate in orthorhombic crystals.
- Arizona ruby=deep-red pyrope (garnet) from Arizona and Utah.
- Arizona spinel=deep-red pyrope (garnet) from Arizona and Utah. Same as Arizona ruby.
- Arkansas diamond=diamond from Arkansas; also quartz crystals from Arkansas.
- Arkansite=brilliant iron-black, opaque brookite, oxide of titanium.
- Armenian stone=(in part) lapis lazuli.

- Arrow points=Indian arrowheads mostly made of quartz, more rarely of obsidian or other fine-grained rock.
- Asparagus stone=pale-yellow apatite.
- Asteria=asteriated sapphire; also any gem showing a six-ray star when cut cabochon.
- Asteriated topaz=asteriated oriental topaz (yellow corundum).
- Australian sapphire=deep inky blue sapphire (corundum).
- Automolite=dark-green to nearly black zinc spinel.
- Aventurine=opaque yellow, brown, or red massive quartz containing inclusions of minute scales of some other mineral, such as mica or iron oxide.
- Aventurine feldspar=sunstone.
- Axstone=nephrite.
- Axinite=aluminum, calcium, iron, and manganese hydrous borosilicate.
- Aztec stone=chalchihuitl.
- Azure quartz=blue quartz.
- Azure stone=lapis lazuli.
- Azulite=pale-blue smithsonite.
- Azurite=blue, copper hydrous carbonate.
- Azurite malachite=azurmalachite.
- Azurmalachite=combination of the copper carbonates azurite (blue) and malachite (green) from the copper mines of Arizona.

B.

- Baffa diamond=quartz crystal.
- Bahias=diamonds from Bahia, Brazil.
- Balas ruby=rose-red or pink spinel.
- Barite=barium sulphate.
- Basanite=velvet black, flinty quartz.
- Bastite=variety of bronzite.
- Beckite=silicified coral shells or fossiliferous limestone replaced by silica.
- Beekite=beckite.
- Bemiscite=salmon-colored feldspar from Bemis, Maine.
- Benitoite=blue barium and titanium silicate.
- Beryl=aluminum and beryllium silicate with small amounts of other elements.
- Beryllonite=beryllium and sodium phosphate.
- Bishop's stone=amethyst.
- Bixbite=red and rose-colored beryl from Utah.
- Black amber=jct.
- Black lava glass=obsidian.
- Black opal=opal in a dark matrix; also opal with vivid colors.
- Blood agate=flesh-red, pink, or salmon-colored agate from Utah.
- Blood jasper=bloodstone.
- Bloodstone=massive dark-green jasper (plasma) with red or blood-colored spots; also hematite (German usage).
- Blue chrysoprase=chalcidony stained blue with chrysocolla.
- Blue john=dark-blue fluorite, tinged with violet.
- Blue malachite=azurite.
- Blue moonstone=blue chalcidony from the Death Valley region, California.
- Blue rock=lapis lazuli from California.
- Blue white=diamond of highest grade.
- Bobrowska garnet=grossularite (garnet).
- Bohemian diamond=rock crystal (quartz).
- Bohemian garnet=dark blood-red pyrope (garnet).
- Bohemian topaz=yellow quartz.
- Bohemian ruby=red or rose quartz.

- Bonamite=translucent apple-green smithsonite from New Mexico.
 Bone turquoise=teeth of fossil animals (mammoths, mastodons, etc.) stained blue by iron phosphate.
 Bottle stone=moldavite.
 Bowenite=unusually translucent serpentine of a cream color.
 Brazilian aquamarine=greenish topaz.
 Brazilian diamond=diamond from Brazil; also clear quartz from Brazil.
 Brazilian emerald=green tourmaline.
 Brazilian pebble=rock crystal (quartz).
 Brazilian peridot=yellow-green tourmaline.
 Brazilian ruby=rose-red or pink topaz, both naturally and artificially colored. Most of the pink or reddish topazes have been artificially colored by heating the dark-yellow ones.
 Brazilian sapphire=light-blue or greenish topaz; also blue tourmaline.
 Brazilian topaz=golden to reddish-yellow topaz; also smoky quartz artificially changed to yellow by heat.
 Briançon diamond=quartz crystal from southeastern France, cut in Briançon.
 Brighton emerald=green bottle glass purposely thrown on beach at Brighton, England.
 Brilliant=diamond.
 Bristol diamond=quartz crystal from Cornwall, England.
 Bronzite=magnesium and iron silicate; variety of enstatite.
 Brookite=hair-brown, yellowish, reddish, or ruby-red, transparent to translucent titanium oxide, in orthorhombic crystals.
 Brown coal=brown or brownish-black coal, often retaining the original wood texture.
 Brown jacinth=vesuvianite.
 Brown spar=ankerite from Chester County, Pennsylvania.
 Bull's-eye=labradorite with a dusky sheen.
 Burma ruby=blood-red ruby (corundum).
 Burmite=amber from Burma.
 Burnt amethyst=purple amethyst changed to brownish-yellow by heat.
 Burnt Brazilian topaz=burnt topaz.
 Burnt topaz=yellow topaz from Brazil which has been changed to pink by heat.
 Byssolite=fine greenish hair-like asbestos or actinolite, inclosed in quartz.
 By-water=yellow-tinted diamond.

C.

- Cabochon=any gem cut round, without facets.
 Cacholong=opaque, procelain-like, milky-white opal.
 Cacholong opal=feebly translucent common opal.
 Caesium beryl=beryl containing several per cent of caesium, one of the rarer alkalis.
 The beryl is generally colorless or pink.
 Cairngorm=yellow to smoky-brown, gray, or black quartz.
 Calamine=zinc hydrous silicate. In England calamine is called smithsonite.
 Calcite=calcium carbonate in rhombohedral (hexagonal) crystals.
 Calcomalachite=mixture of calcium carbonate and malachite, from Arizona.
 California cat's-eye=compact serpentine, sufficiently fibrous to show a silky luster and to yield a cat's-eye effect when cut cabochon, from Tulare County, California.
 California iris=kunzite (spodumene).
 California jade=californite (vesuvianite).
 California moonstone=white or gray chalcedony.
 California onyx=dark-brown aragonite.
 California ruby=garnet.
 California tiger-eye=California cat's-eye.
 Californite=compact, translucent, green vesuvianite.

- Callainite=translucent green aluminum hydrous phosphate (probably variscite).
 Cameo=relief carving on a gem (the opposite of intaglio).
 Canary=yellow diamond.
 Canary beryl=greenish-yellow beryl.
 Cancrinite=complex aluminum, calcium, and sodium hydrous silicate and the carbonate radicle.
 Candle coal=cannel coal.
 Cannel coal=dark grayish-black or brownish-black coal.
 Cape chrysolite=green prehnite from South Africa.
 Cape garnet=bright red-yellow almandite (garnet).
 Cape May diamond=colorless and clear quartz crystal from Cape May, New Jersey.
 Cape ruby=blood-red pyrope (garnet) from South Africa.
 Cape=diamond having a yellowish tinge.
 Carbonado=black diamond, not crystallized.
 Carbuncle=clear deep-red almandite garnet; also any red, scarlet, or crimson garnet cut cabochon. The term is also improperly applied to any red stone especially if cut cabochon.
 Carmazul=oxidized copper ore showing red, brown, blue, and green colors, from Lower California, Mexico; composed of jasper, chalcedony, quartz, hematite, chrysocolla, and malachite.
 Carnelian=translucent red chalcedony.
 Carnelian-onyx=agate with red and white bands.
 Cassinite=pearly, bluish-green aventurine feldspar from Delaware County, Pennsylvania.
 Cassiterite=tin oxide.
 Cat sapphire=dark-blue sapphire.
 Catalinite=beach pebbles from Santa Catalina Island, California.
 Catalina sardonyx=catalinite.
 Catlinite=compact red clay.
 Cat's-eye=any mineral having a changeable luster or showing opalescence without play of colors; also true cat's-eye (chatoyant chrysoberyl); also chatoyant quartz.
 Celestial stone=turquoise.
 Celestial precious stone=olivine from meteorite.
 Cer-agate=chrome-yellow agate from Brazil.
 Ceylon cat's-eye=chrysoberyl cat's-eye.
 Ceylon chrysolite=yellowish-green or greenish-yellow tourmaline.
 Ceylon hyacinth=garnet.
 Ceylon opal=moonstone.
 Ceylon peridot=honey-yellow or yellowish-green tourmaline.
 Ceylon ruby=ruby from Ceylon; also deep-red almandine garnet from Ceylon; also any pale or pink ruby.
 Ceylon sapphire=pale-blue sapphire (corundum).
 Ceylonese zircon=fire-red cloudy zircon.
 Ceylonite=black spinel.
 Chalcedony=compact silica, transparent or translucent, with a waxy luster.
 Chalcedony onyx=agate with white and pale bands.
 Chalcedonyx=chalcedony with alternating stripes of gray and white.
 Chalchihuitl=supposed to have been applied to blue, gray, or green calamine from Mexico, also to turquoise, emerald, prase, green jasper, and jadeite.
 Chalchuite=green turquoise.
 Changeant=labradorite.
 Chert=compact silica, includes flint, hornstone, and jasper.
 Chessy copper=azurite.
 Chessylite=azurite.

- Chesterlite=microcline feldspar from Chester County, Pennsylvania.
Chiastolite=variety of andalusite with crosslike marking.
Chinarump=petrified wood from Arizona.
Chlorastrolite=impure variety of prehnite or thomsonite.
Chloromelanite=dark-green to nearly black jadeite.
Chloropal=green opal from Silesia, Germany. Mineralogically, a hydrous iron silicate.
Chlorophane=variety of fluorite which phosphoresces with a greenish light on being slightly heated as by friction or by the heat of the hand.
Chlorospinel=green spinel.
Chlorutahlite=utahlite (compact variscite).
Chondrodite=silicate of magnesium and iron, with fluorine.
Chrome garnet=uvarovite (garnet).
Chromic iron=chromite.
Chromite=chromium and iron oxide.
Chrysoberyl=aluminum and beryllium oxide.
Chrysoberyllus=greenish-yellow, honey-yellow, or wine-yellow beryl.
Chrysocarmen=very similar to carmazul.
Chrysocolla=green to blue hydrous copper silicate.
Chrysolithus=pale yellowish-green beryl.
Chrysolite=olivine or peridot; also light-golden chrysoberyl (incorrect usage); also improperly applied to any light greenish-yellow to yellowish-green transparent gem.
Chrysoprase=apple-green, olive-green, or whitish-green, translucent chalcedony.
Cinnamon stone=essonite (garnet).
Citrine=golden-yellow quartz.
Cloudy chalcedony=chalcedony with dark cloudy spots in a light-gray transparent base.
Cobaltite=metallic cobalt and iron sulphide and arsenide.
Cobra stone=chlorophane.
Colophonite=brownish-black andradite (garnet), characterized by a resinous luster; iron and calcium silicate.
Colorado ruby=pyrope (garnet). Same as Arizona ruby.
Colorado topaz=topaz from Colorado; also citrine (yellow quartz).
Common opal=translucent, only slightly colored opal without fire or play of colors.
Comptonite=thomsonite.
Congo emerald=diopase from the Congo, Africa.
Copper emerald=diopase.
Copper-ore gem=mixture of various copper minerals, such as green malachite, green or blue chrysocolla, blue azurite, red cuprite.
Copper-pitch ore=compact black or dark-brown mixture of iron and copper oxides.
Coral=hard calcareous structure secreted in or by the tissues of various marine zoophytes. When fossilized, the calcareous matter is often replaced by silica (see beekite).
Coral agate=beekite (see coral).
Cordierite=aluminum, iron, and magnesium hydrous silicate.
Cornish diamond=quartz crystal from Cornwall, England.
Corundum=aluminum oxide.
Corundum cat's-eye=corundum with a bluish, reddish, or yellowish reflection of light of a lighter shade than the stone itself.
Cotterite=quartz having a metallic pearly luster.
Creoline=purplish epidotized trap rock from Massachusetts.
Creolite=banded jasper from Shasta County, California.
Crimson night stone=purple fluorite from Idaho.
Crispate=sagenite.

Crocidolite=fibrous hornblende of a bluish or greenish color, iron and magnesium hydrous silicate. The altered form consists of silica colored yellow and brown with oxide of iron and is called tiger-eye.

Cross stone=chiasmolite (andalusite); also staurolite.

Crystal=colorless transparent quartz; also artificial flint glass.

Cupid's darts=quartz crystal with needle-like inclusions of goethite.

Cyanite=kyanite.

Cymophane=chrysoberyl having a bright spot of light which seems to float over the surface as the stone is moved.

Cyprine=sky-blue vesuvianite.

D.

Damourite=compact mica, a result of the alteration of some preexisting mineral.

Danburite=calcium borosilicate.

Datolite=compact massive calcium hydroborosilicate.

Dauphine diamond=rock crystal (quartz).

Davidsonite=greenish-yellow beryl from vicinity of Aberdeen, Scotland.

Delawarite=aventurine feldspar from Delaware County, Pennsylvania.

Demantoid=olive-green, brown, blackish-green, or light-green grossularite (garnet) from the Ural Mountains, Russia.

Dendrite=having the form of a tree.

Dendritic agate=mocha stone and moss agate.

Diallage=foliated variety of diopside.

Diamond=carbon, in isometric crystals.

Diaspore=aluminum hydrous oxide.

Dichroite=cordierite.

Diopside=calcium and magnesium silicate (pyroxene).

Dioptase=green hydrous silicate of copper.

Disthene=kyanite.

Doublet=consists of a real gem cemented to a piece of glass cut and colored to imitate the real stone.

Dravite=brown tourmaline.

Drop of water=rounded (water-worn), colorless, and transparent pebble of topaz.

Dumortierite=blue or lavender aluminum hydroborosilicate.

Dysluite=yellow or grayish-brown spinel.

E.

Edisonite=mottled blue turquoise.

Egyptian jasper=banded yellow, red, brown, or black jasper.

Egyptian pebble=Egyptian jasper.

Elaeolite=aluminum, sodium, and potassium silicate. Same as nephelite.

Eldoradoite=iridescent quartz from Eldorado County, California.

Elie ruby=red pyrope (garnet) from Elie in Fifeshire, Scotland.

Emerald=green beryl; also improperly applied to any green stone.

Emerald copper=dioptase.

Emerald malachite=dioptase.

Emeraldine=chalcedony artificially colored green.

Emeralite=green and bluish-green tourmaline from San Diego County, California.

Emerandine=dioptase.

Enhydros=hollow nodules of chalcedony partly filled with water.

Enstatite=magnesium silicate.

Epidote=greenish hydrous aluminum, iron, and calcium silicate.

Essonite=yellow variety of grossularite (garnet).

Euclase=bluish or greenish hydrous aluminum and beryllium silicate.

Evening emerald=peridot.

Euxenite=complex mineral containing columbium, titanium, and yttrium, and other elements.

Eye agate=concentric rings of agate with a dark center; also thomsonite.

Eyestone=thomsonite.

F.

Fairy stone=twinned crystal of staurolite, forming a cross.

False amethyst=purple fluorite.

False chrysolite=moldavite.

False diamond=quartz crystal.

False emerald=green fluorite.

False hyacinth=garnet.

False lapis=agate or jasper artificially colored blue.

False lapis lazuli=lazulite.

False ruby=red fluorite.

False sapphire=blue fluorite.

False topaz=yellow quartz; also yellow fluorite.

Fancy=term applied to stones having value other than intrinsic value.

Fancy agates=agates showing delicate markings and intricate patterns.

Fancy stone=unusual stone.

Fashoda garnet=dark brownish-red pyrope (garnet).

Feldspar=group of minerals, including orthoclase, microcline, albite, oligoclase, andesine, labradorite, aluminum and potassium, sodium, or calcium silicates.

Feldspar sunstone=sunstone.

Female sapphire=light-colored sapphire.

Feminine=term applied to stones of a paler color than masculine ones.

Fergusonite=black mineral composed chiefly of yttrium columbate.

Figure stone=agalmatolite.

Fire marble=dark-brown shell marble with brilliant firelike internal reflections.

Fire opal=red or yellowish-red opal.

First bye=diamond with a faint greenish tint.

First water=pure and colorless diamond.

Fish-eye=moonstone.

Fish-eye stone=apophyllite.

Flash opal=opal in which the color shows as a single flash.

Flèches d'amour=sagenite (quartz).

Fleurus diamond=quartz crystal.

Flint=compact silica, opaque, and of dull colors.

Floating light=cymophane.

Flos ferri=aragonite in shapes resembling coral.

Flowers of iron=flos ferri (aragonite).

Flower stone=beach pebbles (chalcedony) with flower patterns.

Fluorspar=fluorite.

Fluorite=calcium fluoride.

Fool's gold=pyrite.

Fortification agate=agate with parallel zigzag lines.

Fossil coral=coral replaced by silica (beckite).

Fossil pineapple=opal pseudomorph after glauconite, from New South Wales.

Fossil turquoise=bone turquoise.

Fowlerite=variety of rhodonite containing zinc.

Franklinite=black iron, manganese, and zinc oxide.

Frost stone=translucent gray chalcedony with pure-white patches or tufts, like snow-flakes, scattered through it, from the Mojave desert, California.

Fuchsite=green muscovite (mica).

G.

Gadolinite=velvety-black yttrium, beryllium, iron silicate, and silicates of other elements.

Gahnite=green zinc spinel.

Garnet=group of silicate minerals. The species are: Almandite, aluminum and iron silicate; andradite, iron and calcium silicate; grossularite, aluminum and calcium silicate; pyrope, aluminum and magnesium silicate; spessartite, aluminum and manganese silicate; uvarovite, chromium and calcium silicate.

Garnierite=green nickel and magnesium hydrous silicate.

Gem=cut and polished precious stone.

Gemstone=gem.

Geneva ruby=synthetic ruby made in Geneva, Switzerland.

Geyserite=siliceous deposit from a geyser.

Gibraltar stone=banded, mottled, or clouded calcium carbonate.

Girasol=corundum cat's-eye with a bluish, reddish, or yellowish reflection of light, lighter in shade than the stone itself, which moves on the surface of the stone like the lines of a starstone; also opal (see girasol opal); also moonstone (feldspar).

Girasol opal=fire opal.

Glass=artificial noncrystallized substance composed of silica and several bases, notably an alkali and lead.

Glass agate=obsidian.

Goethite=iron hydrous oxide.

Golconda diamond=diamond obtained from the regions watered by Krishna and Godavari Rivers but polished in Golconda, India.

Gold=metallic element, often mounted as found, as a nugget.

Gold opal=opal which shows yellowish light over a large area.

Gold quartz=massive quartz inclosing gold.

Golden beryl=clear bright-yellow beryl.

Golden stone=greenish-yellow chrysolite (olivine).

Golden topaz=topaz of a golden-yellow color; also golden-yellow citrine (quartz).

Goldstone=aventurine. An imitation of goldstone consists of glass with included metal filings (fraudulently sold as fire agate).

Gooseberry stone=brownish-green grossularite (garnet).

Goshenite=colorless, white, or bluish beryl from Goshen, Massachusetts.

Goutte d'eau=colorless topaz.

Goutte de sang=blood-red spinel.

Graphic granite=pegmatite composed of quartz and feldspar so arranged as to simulate writing.

Green agate=zonochlorite.

Green garnet=any green garnet; also incorrectly applied to green enstatite from South Africa.

Green starstone=chlorastrolite.

Greenstone=zonochlorite; also chlorastrolite; also californite (vesuvianite).

Grossularite=pale-green or yellow garnet.

Guarnaccino=yellowish-red garnet. Same as vermeille.

Gypsum=calcium hydrous sulphate.

H.

Hair stone=quartz with inclusions of hairlike crystals or fibers of some other mineral. Same as sagenite.

Harlequin opal=opal in which the colors form a minute mosaic or are set in small squares.

Hatchet stone=nephrite.

- Haüynite=complex aluminum, calcium, sodium, and potassium silicate with the sulphate radicle.
- Hawk eye=quartz with inclusions of fine blue parallel fibers of crocidolite.
- Heliodor=beryl from Rossing, Africa; contains a small amount of uranium and is weakly radioactive. By daylight gold-yellow, by artificial light a delicate blue-green.
- Heliolite=sunstone (feldspar).
- Heliotrope=bloodstone (quartz).
- Hematite=iron oxide, either black or red.
- Hemimorphite=calamine (English usage).
- Hercynite=black to dark-green spinel composed of aluminum and iron oxides.
- Herkimer diamond=clear quartz crystal from Herkimer County, New York.
- Hessonite=variety of grossularite (garnet).
- Hetaerolite=brilliant-black radiated mineral composed of the zinc and manganese oxides.
- Hiddenite=green or yellowish-green spodumene.
- Horatio diamond=colorless quartz from Arkansas.
- Hornblende=aluminum, iron, calcium, magnesium silicate, and other elements.
- Hornstone=compact form of silica, like flint but more brittle.
- Hot Springs diamond=quartz.
- Howdenite=chiastolite with fernlike markings, from South Australia.
- Hungarian cat's-eye=quartz cat's-eye.
- Hyacinth=red zircon; also wrongly applied to essonite or other light-colored garnets, to yellowish-red spinel from Brazil, and to red iron-stained quartz.
- Hyacinth of Compostella=quartz, with red hematite inclusions.
- Hyacinthozontes=sapphire-blue beryl.
- Hyalite=clear and colorless opal.
- Hyalosiderite=rich olive-green olivine, containing much iron.
- Hydrophane=opal which becomes transparent in water.
- Hypersthene=magnesium and iron silicate, variety of enstatite.

I.

- Iceland agate=obsidian.
- Iceland spar=clear calcite.
- Iceland agate lava=obsidian.
- Ichthyophthalmite=apophyllite.
- Idocrase=vesuvianite.
- Ilmenite=black iron and titanium oxide.
- Image stone=agalmatolite.
- Imperial jade (Chinese)=green, aventurine quartz.
- Imperial yu-stone=green aventurine quartz.
- Ilvaite=iron and calcium hydrous silicate.
- Inca stone=pyrite.
- Indian agate=moss agate.
- Indian topaz=saffron-yellow topaz; also yellow quartz.
- Indicolite=blue tourmaline.
- Iolanthite=jasper from Crooked River, Crook County, Oreg.
- Iolite=cordierite.
- Iridescent quartz=rock crystal (quartz) filled with fine cracks containing air films which reflect the colors of the rainbow.
- Iris=iridescent quartz; also applied to other iridescent minerals. California iris is spodumene.
- Irish diamond=quartz crystal from Ireland.
- Iron glance=hematite.

- Isle of Wight diamond=quartz crystal.
 Isle Royal greenstone=chlorastrolite.
 Isopyre=very impure opal.
 Italian chrysolite=vesuvianite.
 Iztac Chalchihuitl=white or green Mexican onyx.

J.

- Jacinth=yellow zircon, also improperly applied to essonite and other yellowish garnets.
 Jade=two minerals, nephrite and jadeite. True jade is nephrite; many other minerals are also called jade, such as pectolite, vesuvianite, garnet, bowenite, serpentine, plasma, prehnite, agalmatolite, sillimanite, and saussurite (a rock).
 Jadeite=greenish aluminum and sodium silicate (pyroxene).
 Jager=bluish-white diamond of modern cut. Originally referred to diamond from the Jagersfontein mine, South Africa.
 Jargon=white or grayish-white zircon.
 Jargoon=jargon.
 Jasp agate=intermediate between jasper and chalcedony with predominant opaque jasper.
 Jasper=massive quartz, impure and opaque, containing more iron oxide than agate.
 Jasper opal=deeply colored opal with many included impurities.
 Jasperine=banded and variously colored jasper.
 Jet=pitch-black or velvet-black coal sufficiently hard and compact to receive a brilliant polish.
 Job's tears=local name for peridot from Arizona and New Mexico; also hyalosiderite, a rich olive-green olivine.

K.

- Kashmir sapphire=cornflower-blue corundum.
 Keystoneite=blue chrysocolla or chalcedony colored by copper silicate.
 Kidney stone=nephrite.
 Killiecrankie diamond=limpid topaz from Tasmania.
 King topaz=clear pink, orange, red, yellow, or flesh-colored corundum.
 Kinradite=jasper with spherulites of quartz, from the region around San Francisco, California.
 Kornerupine=aluminum and magnesium silicate.
 Kunzite=transparent lilac spodumene.
 Kyanite=aluminum silicate.

L.

- Labrador feldspar=labradorite.
 Labrador hornblende=hypersthene.
 Labrador spar=labradorite.
 Labrador stone=labradorite.
 Labradorite=feldspar, aluminum, sodium, and calcium silicate.
 Lake George diamond=clear quartz crystal from Herkimer, New York.
 Lake Superior greenstone=chlorastrolite.
 Lapis lazuli=rock composed essentially of the minerals lazurite, haüyite, scapolite, calcite, pyroxene, amphibole, mica, and feldspar.
 Lava=volcanic rock.
 Lavendine=amethyst (quartz).
 Lazulite=blue aluminum, iron, and magnesium hydrous phosphate.
 Lazurite=blue aluminum, calcium, and sodium silicate, with the sulphate radicle.
 Lechosos opal=opal showing deep-green flashes of color or specked with green and carmine; also used for milky opal.

- Leelite=deep flesh-red orthoclase, having a waxy luster.
 Lennilite=greenish feldspar from Lenni Mills, Delaware County, Pennsylvania.
 Leopoldite=porphyry with black spots of manganese oxide.
 Lepidolite=mica, hydrous aluminum, lithium, and potassium silicate, with fluorine.
 Leuco sapphire=white sapphire.
 Lignite=brown coal showing the form and fiber of the original tree.
 Lintonite=zeolite, probably thomsonite, with alternating bands of green and red.
 Lithia emerald=green spodumene.
 Lithoxyle=wood opal showing woody structure.
 Lodestone=magnetite (iron oxide) which shows polarity.
 Love arrows=sagenite (quartz).
 Lucky stone=fairy stone (staurolite).
 Lumachelle=fire marble.
 Lydian stone=basanite (quartz).
 Lynx sapphire=water sapphire (cordierite); also very dark-blue sapphire.
 Lynx stone=cordierite.

M.

- Macle=chiastolite.
 Madeira topaz=citrine quartz.
 Magic stone=hydrophane.
 Magnetite=black magnetic iron oxide.
 Mahogany ore=compact mixture of iron and copper oxides.
 Malachite=green hydrous copper carbonate.
 Malacolite=diopside.
 Male sapphire=deep-colored sapphire.
 Marble=recrystallized limestone or dolomite.
 Marcasite=iron sulphide, in orthorhombic crystals. The same iron sulphide, in isometric crystals, is pyrite.
 Marekanite=mottled brown and black obsidian.
 Mariposite=green compact micaceous aluminum, magnesium, and potassium hydrous silicate.
 Marmorosch diamond=quartz crystal from Marmaros Comitát, Hungary.
 Masculine=term applied to stones of a deep and rich color.
 Matara diamond=colorless or faintly smoky zircon from Ceylon; the pale-brown zircons are sometimes decolorized by heat.
 Matrix=rock surrounding mineral.
 Meerschäum=sepiolite.
 Melanite=dull-black andradite (garnet).
 Menaccanite=ilmenite.
 Menilite=grayish-brown banded, sometimes concretionary, opal from vicinity of Paris, France.
 Mesolite=zeolite similar to thomsonite in composition, aluminum, calcium, sodium, and potassium hydrous silicate.
 Mexican onyx=banded, mottled, or clouded travertine.
 Mica=group of silicate minerals, containing aluminum, and potassium, with water, and other elements.
 Microcline=potash feldspar in triclinic crystals, aluminum and potassium silicate.
 Microlite=essentially a calcium tantalate.
 Mineral turquoise=true turquoise.
 Mocha agate=translucent agate or chalcedony with brown, red, or black dendritic figures like trees or plants.
 Mocha stone=chalcedony with brown, red, or black, treelike inclusions of manganese oxide.

- Mohave moonstone=translucent, lilac-tinted chaledony from the Mohave Desert, California.
- Moldavite=dark-green to black glass resembling obsidian.
- Monazite=cerium phosphate and other rare-earth elements.
- Money stone=local name in Pennsylvania for rutile.
- Montana agate=moss agate from Montana.
- Montana jet=obsidian, from Yellowstone Park.
- Montana ruby=garnet.
- Montana sapphire=corundum; generally applied to dark-blue or greenish-blue sapphire (compare river sapphire).
- Mont Blanc ruby=quartz.
- Moonstone=feldspar (usually oligoclase or the adularia variety of orthoclase) showing a pearly opalescence; also commonly but erroneously applied to some white or gray chaledony and to satin spar (gypsum).
- Mora diamond=probably quartz crystal.
- Morganite=rose-colored beryl from Madagascar.
- Moriah stone=granular and spotted verd antique (serpentine).
- Morian=deep-black almost opaque smoky quartz.
- Moroxite=deep-green or blue-green apatite.
- Mosaic agate=brecciated Mexican onyx.
- Moss agate=chaledony with greenish mosslike or treelike inclusions.
- Moss jasper=opaque and translucent chaledony crowded full with mosslike markings.
- Moss opal=milky opal with black mosslike dendritic inclusions.
- Mother of emerald=prase (quartz).
- Mother-of-opal=rock matrix containing minute disseminated specks of precious opal.
- Mother-of-pearl=the hard iridescent internal layer of various shells.
- Mountain mahogany=banded obsidian.
- Muller's glass=hyalite.
- Myrickite=agate or chaledony containing bright-red inclusions of cinnabar, from the Death Valley region, California.

N.

- Nacre=mother-of-pearl.
- Natrolite=zeolite, aluminum and sodium hydrous silicate.
- Needle stone=sagenite (quartz).
- Nephelite=aluminum, sodium, and calcium silicate.
- Nephrite=true jade, a tough compact fine-grained tremolite (white) or actinolite (green).
- Nevada diamond=obsidian, artificially decolorized.
- New rock=bone turquoise (in distinction from "old rock"=true turquoise).
- New Zealand greenstone=serpentine, richly colored, from New Zealand; also jade or nephrite from New Zealand.
- Nicolo=onyx with a black or brown base and a bluish-white thicker wavy, top layer.
- Nigrine=dark-brown to black rutile with some iron.
- Noble opal=precious opal.
- Novaculite=fine-grained hard chaledonic silica.

O.

- Obsidian=a glassy form of lava.
- Ocean spray=satin spar (gypsum).
- Occidental agate=agate less perfect than oriental agate.
- Occidental amethyst=true amethyst (quartz).
- Occidental cat's-eye=quartz cat's-eye.

- Occidental chalcedony=somewhat opaque chalcedony; more opaque than oriental chalcedony.
- Occidental diamond=rock crystal (quartz).
- Occidental topaz=yellow quartz.
- Occidental turquoise=bone turquoise.
- Octahedrite=titanium oxide in tetragonal crystals, with slightly different properties from rutile.
- Odontolite=bone turquoise.
- Oeil de boeuf=labradorite.
- Old rock=turquoise from Persia.
- Oligoclase=feldspar, aluminum, sodium, and potassium silicate.
- Olivine=magnesium and iron silicate. The word olivine is used as a trade name for green garnet (demantoid from the Ural Mountains), and is also improperly applied to any green stone. The following distinctions are sometimes applied to the mineral olivine: Chrysolite, inclining to yellow; peridot, inclining to yellowish green; olivine, inclining to green.
- Onegite=quartz with inclusions of hair-like crystals of goethite.
- Onyx=banded chalcedony with alternating bands of cloudy milk-white and another color, usually black.
- Oolite=concretionary massive limestone (calcium carbonate) made up of minute spherical grains.
- Opal=amorphous massive form of hydrous silica.
- Opal agate=banded opal having alternate layers of opal and agate.
- Opal jasper=jasper opal.
- Opal onyx=alternate layers of precious and of common opal.
- Opalescent chrysolite=chrysoberyl.
- Opaline=opal matrix.
- Opaline feldspar=labradorite.
- Ophiolite=serpentine.
- Orange topaz=same as Spanish topaz, smoky quartz changed to yellow by heat.
- Oregon jade=californite (vesuvianite).
- Oriental=variety of corundum (not necessarily found in the Orient).
- Oriental agate=finely marked and very translucent agate.
- Oriental alabaster=travertine.
- Oriental amethyst=purple corundum.
- Oriental aquamarine=light-green corundum.
- Oriental cat's-eye=chrysoberyl cat's-eye; also smoky corundum.
- Oriental chalcedony=very translucent chalcedony (compare with occidental chalcedony).
- Oriental chrysoberyl=yellowish-green corundum.
- Oriental chrysolite=greenish-yellow corundum; also chrysoberyl.
- Oriental emerald=green corundum.
- Oriental garnet=almandine (garnet).
- Oriental girasol=girasol (corundum).
- Oriental hyacinth=rose-colored corundum.
- Oriental hyacinth=aurora-red corundum.
- Oriental jasper=bloodstone (quartz).
- Oriental lapis=lapis lazuli.
- Oriental moonstone=pearly corundum.
- Oriental onyx=banded, mottled, or clouded travertine.
- Oriental opal=Hungarian opal carried to the Orient by merchants and then shipped back to Europe.
- Oriental peridot=green corundum.
- Oriental sapphire=(in part) blue corundum.

- Oriental smaragd=green corundum.
 Oriental sunstone=girasol (corundum).
 Oriental topaz=yellow corundum.
 Oriental turquoise=turquoise.
 Orthoclase=potash feldspar in monoclinic crystals, aluminum and potassium silicate.
 Orthose=moonstone (feldspar).
 Ouachita stone=novaculite (whetstone); quartz.
 Ouvarovite=emerald-green garnet colored by chromium.
 Ox-eye=labradorite (feldspar).

P.

- Pagoda stone=agalmatolite.
 Pagodite=agalmatolite.
 Paphos diamond=quartz.
 Parisite=cerium carbonate (and other rare elements), with fluorine.
 Paste=artificial lead glass used to imitate gems.
 Paulite=hyperstene.
 Pealite=opal-like variety of geyselite (silica).
 Pearl=lustrous calcareous concretion with animal membrane between successive layers, deposited in the shells of various mollusks. Not a mineral but an animal product.
 Pearlite=a form of obsidian.
 Pebble=rock crystal (quartz).
 Pecos diamond=quartz from Pecos River, Texas.
 Pectolite=calcium and sodium hydrous silicate.
 Pegmatite=coarsely grained rock composed of quartz and feldspar.
 Pelhamite=variety of serpentine.
 Peliom=cordierite.
 Pennsylvania diamond=iron pyrite.
 Peridot of Ceylon=same as Ceylon peridot, honey-yellow tourmaline.
 Peridot=olivine. (See Olivine.)
 Peristerite=iridescent albite (feldspar).
 Persian lapis=lapis lazuli.
 Perthite=potash feldspar (orthoclase or microcline) with laminae of soda feldspar (albite).
 Peruvian emerald=the best emeralds from Muzo, Colombia.
 Petoskey agate=cemented portions of fossil coral (beckite).
 Petrified honeycomb=beckite.
 Petrified wood=wood replaced by silica.
 Phenacite=silicate of beryllium.
 Phenomenal gem=one which shows a play or change of color by artificial light, or shows a movable line of light.
 Piedmontite=brownish-red variety of epidote.
 Pin fire opal=opal in which the area of the individual colors is very small.
 Pink topaz=topaz either naturally pink or artificially colored pink by heating the yellow or brown varieties.
 Pink wollastonite=lilac-colored pyroxene (diopside) from the region of San Francisco, California.
 Pipestone=catlinite (compact red clay).
 Pisolite=concretionary massive limestone, similar to oolite but made up of larger spherical grains.
 Pistacite=greenish epidote.
 Pitch opal=brown opal with a pitchy luster.
 Pitchstone=obsidian of a pitchy luster.

Plasma=massive translucent quartz, dark grass-green in color, sometimes with white or yellow inclusions of celadonite or of delessite.

Pleonaste=black spinel.

Polycrase=black mineral similar in composition to euxenite.

Porcelain jasper=a naturally indurated clay.

Porphyry=rock, variegated in structure, with individual crystals much larger than the fine-grained matrix.

Potstone=soapstone (impure talc).

Prase=massive, translucent, and spotted quartz of a green to leek-green color caused by inclusions of minute crystals of actinolite or other minerals.

Prase opal=apple-green translucent opal.

Precious coral=red coral.

Precious opal=opal showing a play of colors.

Precious schorl=tourmaline.

Prehnite=greenish aluminum and calcium hydrous silicate.

Prismatic moonstone=clouded chalcedony (quartz) from Mohave Desert, California.

Prismatic quartz=cordierite.

Prosopite=aluminum and calcium hydrous fluoride.

Pseudochrysolite=moldavite.

Pseudodiamond=quartz crystal.

Pseudoemerald=malachite.

Pyrite=iron sulphide in isometric crystals.

Pyrope=blood-red garnet, aluminum and magnesium silicate.

Pyroxene=group of complex silicates of aluminum, iron, calcium, magnesium, and other elements.

Q.

Quartz=crystallized silica.

Quebec diamond=quartz crystal.

Quinzite=rose-colored common opal.

R.

Radio opal=opal of a smoky color caused by organic inclusions or impurities.

Radiumite=mixture of black pitchblende, yellow uranotile, and orange gummitite.

Rainbow agate=agate which shows iridescence when cut across the concentric structure.

Rainbow quartz=iridescent quartz.

Rattle boxes=limonite geodes.

Realgar=orange arsenic sulphide.

Reconstructed gem=one artificially made by fusing and recrystallizing fragments of natural gems.

Red stone=ruby.

Resin opal=opal with a resinous luster.

Rhinestone=rock crystal (quartz).

Rhodochrosite=pink manganese carbonate.

Rhodolite=rose-colored garnet, between pyrope and almandite; aluminum, iron, and magnesium silicate; from Macon County, North Carolina.

Rhodonite=pink manganese silicate.

Riband agate=agate with parallel layers.

Riband jasper=jasper with differently colored alternating bands.

Ribbon agate=banded agate.

Ring agate=agate with differently colored bands arranged in concentric circles.

Ripe diamond=true diamond (see unripe diamond).

River agate=moss-agate pebbles found in brooks and streams.

River sapphire=light-colored sapphire from Montana.

- Rock crystal=clear quartz crystal.
 Rock ruby=red garnet (pyrope).
 Rocky Mountain ruby=garnet.
 Romanovite=brown grossularite (garnet), aluminum and calcium silicate.
 Rosaline=thulite (pink zoisite).
 Rose quartz=massive rose-red to pink quartz.
 Rose topaz=pink topaz.
 Roselite=pink garnet. Mineralogically a calcium and cobalt hydrous arsenate.
 Royal topaz=blue topaz.
 Rubasse=quartz artificially stained red.
 Rubellite=pink and red tourmaline.
 Rubicelle=yellow or orange-red spinel.
 Rubino-di-rocca=red garnet having a tinge of violet.
 Rubolite=red opal from Texas.
 Ruby=red corundum.
 Ruby spinel=deep-red spinel.
 Ruin aragonite=brecciated Mexican onyx.
 Rutile=titanium oxide.

S.

- Sabalite=yellowish to greenish banded phosphatic material, similar to or inclosing variscite, from Utah.
 Sacred turquoise=pale-blue smithsonite.
 Sagenite=transparent quartz with inclusions of hairlike or needle-like crystals or fibers of some other mineral, generally rutile.
 Samarskite=black mineral of complex composition, essentially a yttrium, uranium, and iron columbate.
 Sandy sard=sard dotted with darker spots (quartz).
 Saphir d'eau=water sapphire (blue cordierite).
 Sapparé=transparent kyanite.
 Sapphire=blue corundum. The name is also applied to colorless and colored (except red) corundum.
 Sapphire quartz=blue quartz.
 Sapphirine=blue chalcedony, blue quartz; also blue spinel; aluminum and magnesium silicate.
 Sard=chalcedony of a rich brown color, with a reddish tint; brownish-red or dark-brown carnelian (sardoine).
 Sardoine=brownish-red or dark-brown carnelian.
 Sardonyx (sard-onyx)=white and brown banded chalcedony.
 Satellite=serpentine cat's-eye.
 Satin spar=finely fibrous gypsum having a pearly opalescence; also finely fibrous calcite having a silky luster; also finely fibrous aragonite having a silky luster.
 Saussurite=greenish to white or gray rock composed chiefly of zoisite.
 Saxon chrysolite=pale wine-yellow or greenish-yellow topaz tinged with green.
 Saxon topaz=pale wine-yellow topaz; also citrine (quartz).
 Scapolite=group of minerals composed of aluminum, calcium, and sodium silicates, with the chloride, carbonate, or sulphate radicles.
 Scarab=precious stone inscribed with symbols, engraved like a beetle.
 Schaumberg diamond=quartz crystal from Schaumberg, Hesse, Germany.
 Schiller quartz=quartz cat's-eye.
 Schiller spar=bastite (enstatite).
 Schnecken topaz=Saxon topaz.
 Schorl=black tourmaline.
 Schorlomite=black garnet containing considerable titanium.

- Scoopstone=amber collected from seaweed.
 Scotch topaz=smoky quartz.
 Seastone=amber cast upon shore by sea.
 Selenite=colorless, transparent gypsum.
 Semicarnelian=yellow agate.
 Semiopal=colorless to strongly colored somewhat opaque, common opal.
 Semiturquoise=soft pale-blue turquoise.
 Sepiolite=magnesium hydrous silicate.
 Serpentine=magnesium hydrous silicate.
 Serpentine cat's-eye=serpentine showing when cut a changeable luster or opalescence without play of colors.
 Siam=dark-red ruby.
 Siam ruby=dark-red ruby from Siam; also red spinel.
 Siberian amethyst=rich or dark-colored amethyst.
 Siberian aquamarine=very light greenish-blue beryl.
 Siberian chrysolite=demantoid (garnet).
 Siberian ruby=red tourmaline.
 Siberian topaz=very pale blue or bluish-white topaz.
 Siberite=violet-red tourmaline.
 Siderite=sapphirine (blue quartz). Mineralogically, an iron carbonate.
 Siliceous malachite=green chrysocolla.
 Silicified wood=wood replaced by silica.
 Sinople=quartz having red hematite inclusions.
 Slave's diamond=colorless topaz.
 Smaragdite=green variety of amphibole, like actinolite; also applied to other green stones, as the emerald, fuchsite, etc.
 Smaragdus=smaragdite.
 Smithsonite=zinc carbonate. In England this zinc carbonate is called calamine.
 Smoky quartz=quartz crystals of a smoky or brown color.
 Smoky topaz=true topaz of a smoky color; also more commonly smoky quartz.
 Sobrisky opal=opal from the Lead Pipe Spring district in the Death Valley region, California.
 Sodalite=aluminum and sodium silicate, with chlorine, generally blue.
 Soldier's stone=amethyst.
 Spanish emerald=emerald of the finest quality (presumably from South America).
 Spanish lazulite=cordierite.
 Spanish topaz=smoky quartz changed to yellow by heat.
 Specular iron ore=hematite.
 Spessartite=yellow, brown, or red garnet, aluminum and manganese silicate.
 Sphaerulite=variety of obsidian.
 Sphalerite=zinc sulphide.
 Spheue=titanite.
 Spinel=group of minerals composed of aluminum, iron, chromium, magnesium, or zinc oxides. The name spinel is also applied to the species of this group which consists chiefly of aluminum and magnesium oxides.
 Spinel ruby=red spinel.
 Spinel sapphire=blue spinel.
 Spodumene=aluminum and lithium silicate.
 St. Stephen stone=translucent chalcedony with round blood-red spots through it.
 Stalactite=calcium carbonate in pendent masses deposited in caverns by evaporating water.
 Stalagmite=calcium carbonate deposited from evaporating water on the floors of caverns.

- Star stone=starolite (quartz).
 Star ruby=ruby (corundum) showing a star of light.
 Star sapphire=grayish-blue sapphire (corundum) showing a star of light.
 Star topaz=asteriated oriental topaz (yellow corundum).
 Starolite=asteriated quartz.
 Staurolite=aluminum, iron, and magnesium hydrous silicate.
 Steinheilite=cordierite.
 Stibiotantalite=antimony tantalate.
 Succinite=amber; also amber-colored grossularite (garnet).
 Sulphur diamond=pyrite.
 Sun opal=fire opal.
 Sunstone=feldspar (usually oligoclase or labradorite) containing inclusions of minute scales of iron oxide.
 Swiss lapis=agate or jasper artificially colored blue.
 Synthetic gem=one artificially made from chemicals.
 Syrian garnet=almandite (garnet) of a violet shade.

T.

- Tabasheer=amorphous opal-like silica deposited in the joints of bamboo.
 Tauridan topaz=very pale blue topaz.
 Taxoite=serpentine from Chester County, Pennsylvania.
 Test stone=basanite (jasper).
 Texas agate=agate jasper from Texas.
 Thetis hairstone=transparent quartz with inclusions of hairlike crystals of green actinolite.
 Thomsonite=zeolite, aluminum, calcium, and sodium hydrous silicate.
 Thulite=rose-red zoisite.
 Tiger-eye=yellow to brown, altered crocidolite.
 Titanite=calcium and titanium silicate.
 Toad's-eye tin=concentric cassiterite. Same as wood tin but on a smaller scale.
 Topaz=aluminum silicate, with fluorine. Most of the ordinary topaz of commerce is "false topaz" or yellow to brown quartz. Much of the "yellow quartz" is smoky quartz artificially changed from brown to yellow by heat. The term topaz is also improperly applied to any yellow stone.
 Topaz cat's-eye=yellow corundum showing an elongated or round patch of opalescent light.
 Topazolite=colorless, yellowish, or greenish andradite (garnet).
 Touchstone=basanite (jasper).
 Tourmaline=group of closely related minerals which are complex hydroboro-silicates of aluminum and one or more other bases, such as iron, manganese, calcium, magnesium, sodium, or lithium.
 Trainite=impure banded variscite.
 Tree agate=mocha stone.
 Tree stone=mocha agate.
 Trenton diamond=quartz crystal from Herkimer County, New York.
 Trilobite=fossil.
 Triphane=yellow or greenish-yellow spodumene.
 Troostite=pink to gray willemite containing some manganese.
 Turquoise=aluminum and copper hydrous phosphate.
 Turkis=turquoise.
 Turtle back=chlorastrolite; also matrix turquoise; also matrix variscite.

U.

- Unripe diamond=quartz.
 Ural chrysoberyl=alexandrite.

Uralian emerald=Siberian demantoid (green garnet).

Utahlite=compact variscite.

Uvarovite=green garnet containing chromium.

V.

Vallum diamond=quartz crystals from the Tanjore district, Madras Presidency, India.

Variolite=dark-green orthoclase (feldspar) containing lighter-colored globular particles.

Variscite=green hydrous phosphate of aluminum.

Vegetable fossil=amber.

Verd antique=variegated serpentine.

Verdite=green rock, composed chiefly of fuchsite (green muscovite containing chromium) or talc.

Verdolite=talcose-dolomitic breccia rock from New Jersey.

Vermeille=orange-red almandite (garnet); also orange-red spinel.

Vermilion opal=milky opal impregnated with cinnabar.

Vermilite=vermilion opal.

Vesuvian gem=vesuvianite.

Vesuvianite=complex silicate, chiefly of aluminum and calcium.

Vinegar spinel=yellowish-red spinel.

Violane=dark violet-blue diopside (pyroxene), from Piedmont, Italy.

Violet stone=cordierite.

Violite=compact purple chalcedony from San Diego County, California.

Volcanic chrysolite=vesuvianite.

Volcanic glass=obsidian.

Vulpinite=anhydrite.

W.

Wabanite=banded cream to black and gray to purple chocolate-colored slate from Massachusetts.

Wardite=aluminum hydrous phosphate.

Water agate=shell of chalcedony containing bubble of water.

Water chrysolite=moldavite.

Water opal=moonstone (feldspar).

Water sapphire=true water sapphire is cordierite; also white topaz.

Water stone=hydrolite (opal).

Wax agate=yellow agate, with a pronounced waxy luster.

Wax opal=yellow opal with a waxy luster.

Wernerite=scapolite.

White carnelian=cloudy, milk-white, or very pale reddish or yellowish chalcedony.

White emerald=caesium beryl.

White jade=white nephrite; also compact white garnet; also white californite (vesuvianite).

White sapphire=colorless corundum; also quartz.

White topaz=colorless topaz; also quartz.

Willemite=zinc silicate.

Williamsite=variety of serpentine of a rich blackish oil-green color.

Wiluite=green vesuvianite; also yellowish-green to greenish-white garnet.

Wilsonite=purplish-red scapolite.

Wolf's eye=moonstone (feldspar).

Wolf's eye stone=crocidolite.

Wollastonite=calcium silicate.

Wood agate=wood petrified or replaced by agate.

Wood opal=wood silicified by opal.

Wood stone=silicified wood.

Wood tin=cassiterite with a concentric structure.

World's eye=hydrophane (opal).

X.

Xanthite=dark yellowish-brown vesuvianite from Amity, New York.

Y.

Yogo sapphire=dark-blue corundrum from Yogo Gulch, Montana.

Yu stone=jade.

Z.

Zincite=zinc oxide, mostly red.

Zircon=zirconium silicate.

Zoisite=aluminum and calcium hydrous silicate.

Zonite=variously colored chert or jasper, from Arizona.

Zonochlorite=banded prehnite, similar to chlorastrolite.

PART 2.—MINERAL NAMES.

A.

Allanite.

Amphibole=actinolite, axstone, byssolite, crocidolite, hawk's-eye, hornblende, jade, kidney stone, nephrite, New Zealand greenstone, smaragdite, smaragdus, tremolite, wolf's-eye stone.

Anatase.

Andalusite=chiastolite, cross-stone, macle, howdenite.

Anhydrite=vulpinite.

Ankerite=brown spar.

Apatite=moroxite, asparagus stone.

Apophyllite=fisheye stone, ichthyophthalmite.

Aragonite=alabaster, California onyx, flos ferri, flowers of iron, Gibraltar stone, iztac chalchihuitl, Mexican onyx, mosaic agate, oriental alabaster, oriental onyx, ruin aragonite, satin spar, stalactite, stalagmite, verd antique. (See also calcite.)

Axinite.

Azurite=blue malachite, chessy copper, chessylite.

Azurmalachite.

B.

Barite.

Benitoite.

Beryl=aeroides, amethyste basaltine, aquamarine, aquamarine chrysolite, bixbite, caesium beryl, canary beryl, chalchihuitl, chrysoberyllus, chrysolithus, davidsonite, emerald, golden beryl, goshenite, heliodor, hyacinthozontes, morganite, Peruvian emerald, Siberian aquamarine, smaragdite, Spanish emerald, white emerald.

Beryllonite.

Bone turquoise=fossil turquoise, new rock, occidental turquoise, odontolite.

Brookite=arkansite.

C.

Calamine=Aztec stone, chalchihuitl, hemimorphite.

Calcite=agate, calcomalachite, fire marble, Iceland spar, lumachelle, marble, Mexican onyx, onyx marble, Oriental alabaster, oolite, pisolite, satin spar.

Cancrinite.

Cassiterite=toad's-eye tin, wood tin.

Chondrodite.

Chromite=chromic iron.

Chrysoberyl=alexandrite, cat's-eye, Ceylon cat's-eye, chrysolite, cymophane, floating light, opalescent chrysolite, oriental cat's-eye, Ural chrysoberyl.

Chrysocolla=keystonite, siliceous malachite.

Clay=catlinite, pipestone, porcelain jasper.

Coal=anthracite, black amber, brown coal, candle coal, cannel coal, jet, lignite.

Cobaltite.

Copper ore gem=carmazul, chrysoarmen, copper pitch ore, mahogany ore.

Cordierite=dichroite, iolite, lynx-stone, peliom, prismatic quartz, saphir d'eau, Spanish lazulite, steinheilite, violet stone, water sapphire.

Corundum=adamantine spar, asteria, asteriated topaz, Australian sapphire, Burma ruby, cat sapphire, Ceylon ruby, corundum cat's-eye, female sapphire, girasol, Kashmir sapphire, king topaz, leuco-sapphire, lynx sapphire, male sapphire, Montana sapphire, oriental, oriental amethyst, oriental aquamarine, oriental cat's-eye, oriental chrysoberyl, oriental chrysolite, oriental emerald, oriental girasol, oriental hyacinth, oriental moonstone, oriental peridot, oriental sapphire, oriental smaragd, oriental sunstone, oriental topaz, red stone, river sapphire, ruby, sapphire, star ruby, star sapphire, Siam, star topaz, topaz cat's-eye, white sapphire, Yogo sapphire.

D.

Danburite.

Datolite.

Diamond=Bahia, blue-white, brilliant, by-water, canary, cape, carbonado, first bye, first water, Golconda, jager, ripe-diamond.

Diaspore.

Dioptase=achirite, Congo emerald, copper emerald, emerald copper, emerald malachite, emerandine.

Dumortierite.

E.

Epidote=piedmontite, pistacite.

Euclase.

Euxenite.

F.

Feldspar=adularia, albite, albite moonstone, amazonstone, andesine, aventurine feldspar, bemiscite, bull's-eye, cassinite, Ceylon opal, changeant, chesterlite, delawarite, fisheye, girasol, heliolite, Labrador spar, Labrador stone, labradorite, leelite, lennilite, microcline, moonstone, oeil de boeuf, oligoclase, opaline feldspar, orthoclase, orthose, ox-eye, peristerite, perthite, sunstone, variolite, water opal, wolf's eye.

Fergusonite.

Fluorite=blue john, chlorophane, cobra stone, crimson night stone, false amethyst, false emerald, false ruby, false sapphire, false topaz, fluorspar.

Fossil=beckite, beekite, fossil coral, Petoskey agate, petrified honeycomb, trilobite.

Franklinite.

G.

Gadolinite.

Garnet=Adelaide ruby, almandite, American ruby, andradite, Arizona ruby, Arizona spinel, Bobrowska garnet, Bohemian diamond, Bohemian garnet, California ruby, Cape ruby, carbuncle, Ceylon hyacinth, Ceylon ruby, chloromelanite, chrome garnet, cinnamon stone, colophonite, Colorado ruby, demantoid, Elie ruby, essonite, false hyacinth, Fashoda garnet, gooseberry stone, grossularite, guarnaccino, hessonite, hyacinth, jacinth, jade, melanite, Montana ruby, olivine, oriental garnet, ouvarovite, pyrope, rhodolite, rock ruby, Rocky Mountain ruby, roman-

sovite, roselite, rubino-di-rocca, schorlomite, Siberianchrysolite, spessartite, succinite, Syrian garnet, topazolite, Uralian emerald, uvarovite, vermeille, white jade, wiluite.

Garnierite.

Goethite.

Gold.

Gypsum=alabaster, moonstone, ocean spray, satin spar, selenite.

II.

Häüynite.

Hematite=bloodstone, iron glance, specular iron ore.

Hetaerolite.

I.

Ilmenite=menaccanite.

Ilvaite.

K.

Kornerupine.

Kyanite=cyanite, disthene, sapparé.

L.

Lapis lazuli=Armenian stone, azure stone, blue rock, oriental lapis, Persian lapis.

Lazulite=false lapis lazuli.

Lazurite.

Limonite=rattlebox.

M.

Magnetite=lodestone.

Malachite=pseudo-emerald.

Marcasite.

Mesolite.

Mica=agalmatolite, damourite, figure stone, fuchsite, image stone, lepidolite, mario-
posite, pagoda stone, pagodite, smaragdite, verdite.

Microlite.

Moldavite=bottle stone, false chrysolite, pseudo-chrysolite, water chrysolite.

Monazite.

N.

Natrolite.

Nephelite.

O.

Obsidian=arrow points, black lava glass, glass agate, Iceland agate, Iceland agate
lava, marekanite, Montana jet, mountain mahogany, Nevada diamond, pearlite,
pitchstone, sphaerulite, volcanic glass.

Octahedrite=anatase.

Olivine=celestial precious stone, chrysolite, evening emerald, golden stone, hyalosid-
erite, Job's-tears, peridot.

Opal=amber opal, black opal, cacholong opal, common opal, fire opal, flash opal,
flash fire opal, fossil pineapple, girasol opal, gold opal, harlequin opal, hyalite,
hydrophane, isopyre, jasper opal, lechosos opal, lithoxyle, magic stone, menilite,
moss opal, mother-of-opal, Muller's glass, noble opal, opal agate, opal jasper, opal
onyx, opaline, oriental opal, pealite, pin fire opal, pitch opal, prase opal, precious
opal, quinzite, radio opal, resin opal, rubolite, semiopal, Sobrisky opal, sun opal,
tabasheer, vermilion opal, vermilitite, water stone, wax opal, wood opal, world's eye.

P.

Parisite.

Pectolite=jade.

Phenacite.

Pitchblende=radiumite.

Polycrase.

Prehnite=Cape chrysolite, chlorastrolite, green agate, green star stone, greenstone, Isle Royal greenstone, Lake Superior greenstone, turtleback, zonochlorite. (See also thomsonite.)

Prosopite.

Pyrite=alpine diamond, fool's gold, Inca stone, Pennsylvania diamond, sulphur diamond.

Pyrophyllite=agalmatolite.

Pyroxene=alalite, bastite, bronzite, chalchihuitl (jadeite), diopside, enstatite, green garnet (enstatite), hypersthene, jade, jadeite, Labrador hornblende, malacolite, New Zealand greenstone, paulite, pink wollastonite, Schillerspar, violane, yu stone.

Q.

Quartz=agate, agate jasper, Alaska diamond, Alençon diamond, Aleppo stone, amberine, amethyst, amethystine quartz, Ancona ruby, apricotine, Arkansas diamond, arrow points, aventurine, azure quartz, Baffa diamond, basanite, beekite, beekite, bishop's stone, bloodstone, blood jasper, blue chrysoptase, blue moonstone, Bohemian diamond, Bohemian topaz, Bohemian ruby, Brazilian diamond, Brazilian pebble, Brazilian topaz, Briarçon diamond, Bristol diamond, burnt amethyst, cacholong, cairngorm, California moonstone, Cape May diamond, carnelian, carnelian-onyx, catalinite, Catalina sardonyx, cat's-eye, cer-agate, chalchihuitl, chalcedony, chalcedony onyx, chalcedony, chert, china, rump, chloropal, chrysoptase, Colorado topaz, Cornish diamond, cotterite, creolite, crispite, crystal, cupid's darts, Dauphiné diamond, dendritic agate, Egyptian jasper, Egyptian pebble, eldoradite, emeraldine, enhydros, eye agate, false diamond, false lapis, false topaz, fancy agate, feminine carnelian, flèches d'amour, Fleurus diamond, flint, flower stone, fortification agate, fossil coral, frost stone, geyselite, gold quartz, golden topaz, hairstone, heliotrope, Herkimer diamond, Horatio diamond, hornstone, Hot Springs diamond, hyacinth, Hungarian cat's-eye, hyacinth of Compostella, Imperial jade, Imperial yu stone, Indian agate, Indian topaz, iolanthite, iridescent quartz, iris, Irish diamond, Isle of Wight diamond, jasp-agate, jasper, jasperine, kinradite, Lake George diamond, lavendine, love arrows, lydian stone, Madeira topaz, Marmorosch diamond, masculine carnelian, milky quartz, mocha stone, Mohave moonstone, Montana agate, Mont Blanc ruby, moonstone, Mora diamond, morion, moss agate, moss jasper, mother of emerald, myrickite, needlestone, nicolo, novaculite, occidental agate, occidental amethyst, occidental cat's-eye, occidental chalcedony, occidental diamond, occidental topaz, onegite, onyx, orange topaz, oriental agate, oriental chalcedony, oriental jasper, ouachita stone, Paphos diamond, pebble, Pecos diamond, petrified wood, plasma, prase, prismatic moonstone, pseudo diamond, Quebec diamond, rainbow agate, rainbow quartz, rhinestone, riband agate, riband jasper, ribbon agate, ring agate, river agate, rock crystal, rose quartz, rubasse, sagenite, sandy sard, sapphire quartz, sapphirine, sard, sardoine, sardonyx, Saxon topaz, Schaumberg diamond, Schiller quartz, Scotch topaz, semicarnelian, Siberian amethyst, siderite, sinople, silicified wood, smoky quartz, smoky topaz, soldier's stone, Spanish topaz, St. Stephen stone, star stone, starolite, Swiss lapis, test stone, Texas agate, Thetis hairstone, tiger-eye, topaz, touchstone, tree agate, tree stone, Trenton diamond, unripe diamond, Vallum diamond, Venus hairstone, violite, water agate, wax agate, white carnelian, white sapphire, white topaz, wood agate, woodstone, zonite.

R.

Realgar.

Rhodochrosite.

Rhodonite=fowlerite.

Rock=agrite, catlinite, clay, creoline, graphic granite, lapis lazuli, lava, leopard-ite, matrix, mother-of-opal, novaculite, obsidian, pegmatite, pipestone, porcelain-jasper, porphyry, potstone, saussurite (jade), verdolite, volcanic lava, wabanite.
Rutile=money stone, nigrine.

S.

Samarskite.

Sapphirine.

Scapolite=wernerite; wilsonite.

Sepiolite=meerschauum.

Serpentine=bowenite, California cat's-eye, California tiger-eye, jade, moriah stone, New Zealand greenstone, ophiolite, pelhamite, satellite, serpentine cat's-eye, taxoite, verd antique, williamsite.

Sillimanite=jade.

Smithsonite=azulite, bonamite, sacred turquoise.

Sodalite.

Sphalerite.

Spinel=Alabandine ruby, almandine spinel, automolite, balas ruby, ceylonite, chlorospinel, chromite, dysluite, franklinite, gahnite, goutte de sang, hercynite, hyacinth, magnetite, pleonaste, rubicelle, ruby spinel, sapphirine, Siam ruby, spinel ruby, spinel sapphire, vermeille, vinegar spinel.

Spodumene=California iris, hiddenite, kunzite, lithia emerald, triphane.

Staurolite=cross stone, fairy stone, lucky stone.

Stibiotantalite.

T.

Talc=verdite.

Thomsonite=comptonite, eye agate, eyestone, lintonite.

Titanite=sphene.

Topaz=aquamarine topaz, Brazilian aquamarine, Brazilian ruby, Brazilian sapphire, Brazilian topaz, burnt Brazilian topaz, burnt topaz, drop of water, golden topaz, goutte d'eau, Indian topaz, Killiecrankie diamond, pink topaz, royal topaz, Saxon chrysolite, Saxon topaz, Schnecken topaz, Siberian topaz, slave's diamond, tauridian topaz, water sapphire.

Tourmaline=achroite, andalusite, aphrizite, Brazilian emerald, Brazilian peridot, Brazilian sapphire, Ceylon chrysolite, Ceylon peridot, dravite, emeralite, indicolite, peridot of Ceylon, precious schorl, rubellite schorl, Siberian ruby, siberite.

Turquoise=celestial stone, chalchihuitl, chalchuite, edisonite, mineral turquoise, old rock stone, oriental turquoise, semiturquoise, turkis, turtleback.

V.

Variscite=amatrice, callainite, chlorutahlite, sabalite, trainite, turtleback, utahlite.

Vesuvianite=American jade, brown jacinth, California jade, californite, cyprine, greenstone, idocrase, Italian chrysolite, jade, Oregon jade, Vesuvian gem, volcanic chrysolite, volcanic scoria, white jade, xanthite.

W.

Wardite.

Willemite=troostite.

Wollastonite.

Z.

Zincite.

Zircon=Ceylonese zircon, hyacinth, jacinth, jargon, jargoon, matara diamond.

Zoisite=rosaline, thulite.

APPENDIX 5.

INDUSTRIAL USES OF PRECIOUS STONES.¹

In the following paragraphs are mentioned some industrial uses of minerals of gem quality. In addition to ornamentation, all gem minerals are of value as specimens for collections, for use in standardization (for example, fluorite and quartz as standards of densities and of refractive indices), and as sources of material for investigation, both industrial and scientific. These uses are therefore not always repeated under the different mineral names. Ornamentation itself covers a variety of utilization, such as for jewelry, knife handles, paper weights, and pipes (meerschaum).

Agate.—Mechanical bearings and supports, scale bearings, balls for water meters, mortars for laboratory use, spatulas, paper knives, playing marbles, and small ornaments.

Azurite.—Ore of copper; pigment for paint.

Azuralachite.—Ore of copper.

Calcite.—See Iceland spar.

Chromite.—Ore of chromium.

Chrysocolla.—Ore of copper.

Cobaltite.—Ore of cobalt.

Corundum.—See Sapphire.

Diamond.—Cutting, grinding, engraving, boring, and polishing material; supports for bearings and pivots; dies for wire drawing; tips for phonograph needles.

Epidote.—For coloring artificial slate and roofing material.

Fluorite.—See Optical fluorite.

Franklinite.—Ore of manganese and zinc.

Garnet.—Abrasive; for watch jewels or jeweled bearings; as tared weights.

Garnierite.—Ore of nickel.

Gypsum.—Used in manufacture of artificial pearls—the so-called "Roman pearls."

Hematite.—Ore of iron.

Iceland spar.—Iceland spar is a variety of calcite, clear and transparent and unusually free from imperfections and impurities. Transparent crystals or cleavage pieces of calcite of any appreciable size are very rare, and as Iceland has furnished almost all of such material used the name Iceland spar has been given it.

Elongated cleavage rhombohedrons of Iceland spar are used in the manufacture of Nicol prisms, which are an essential part of optical instruments requiring plane polarized light, as, for example, certain microscopes, dichroscopes, and saccharimeters. The material, on account of its simple chemical composition and purity, finds application in chemical standardization. Iceland spar is also used in the manufacture of some kinds of glass, and some of it is sold as mineral specimens.

Pieces of Iceland spar, either in single untwinned crystals or parts of such crystals or in homogeneous untwinned cleavage rhombohedra, which are large enough to yield a rectangular prism at least 1 inch long and half an inch thick each way and which possess the properties described below, are suitable for optical purposes. The colorless material must be so clear and transparent that it is limpid and pellucid.

¹ Dr. W. T. Schaller, Mineral Resources of the United States, 1915.

It must not be partly opaque on account of numerous cracks or fractures, must not show any internal, iridescent, or rainbow colors due to incipient cracks along fracture lines, nor any cleavage, nor twinning planes. Neither can there be any capillary or larger tubelike cavities, nor cavities or bubbles of any shape, nor inclusions, as isolated particles, veins, or clouds, composed of minute crystals of some other mineral or of any kind of foreign substance. The spar should not be discolored or stained by the presence of any clay, iron oxide, or other material. It should be noted that many of the inclusions and imperfections of Iceland spar are not always scattered irregularly through the mineral or even segregated in distinct masses, but frequently lie in a distinct but very thin plane which can hardly be seen if looked at on edge. In examining a piece of Iceland spar for defects the piece should therefore be turned in all directions while held to the light.

The material suitable for optical uses naturally brings the highest prices, as it has to be at least of the dimensions already given. Specimen material is generally of a larger size. The material used for standardization, chiefly chemical, need be of no special size, and the smaller pieces are as usable as the larger ones.¹

Although calcite is, next to quartz, the commonest mineral, the only locality outside of Iceland known to produce the variety Iceland spar in commercial quantity is in Montana, about 9 miles from Gray Cliff, Sweet Grass County, on the main line of the Northern Pacific Railway. The spar occurs in a nearly vertical fissure vein from 3 to 8 feet thick, which strikes northwest, traversing a gneissic rock for several miles.

Jasper.—See Agate.

Malachite.—Ore of copper, pigment for paint.

Mariposite.—Pigment for paint.

Meerschaum.—Pipe bowls; cigar and cigarette holders.

Optical fluorite.—Fluorite, commonly called fluorspar, is a common mineral but is very seldom found in pieces clear enough and large enough to be of special use in the manufacture of certain optical lenses and prisms. Fluorite of the requisite qualities, as described below, suitable for such use is known as "optical fluorite." Any deposit of fluorite may yield a small quantity of such material, but at present about the only localities known to produce it are southern Illinois; Meiringen, Switzerland; and Obira, Bungo, Japan. Optical fluorite is cut into lenses and placed between glass lenses. It forms the apochromatic objective for microscopes and similar optical instruments, the fluorite lens correcting the spherical and chromatic errors of the glass lens systems. This result is due to the low refractive power, weak color dispersion, and single refraction of fluorite. These apochromatic lenses represent the finest type of microscope objectives made. The use of such a fluorite lens greatly increases the value of a microscope and if optical fluorite were more abundant many more microscope objectives would be equipped with such lenses.

Optical fluorite is also used in the lenses of certain telescopes, in making prisms for spectrographs in ultra-violet work, and in other optical apparatus where transparency in the ultra-violet and infra-red parts of the spectrum is necessary.

¹ The optical variety of Iceland spar produced in the United States, sold, a pound, for \$3 to \$4 in 1914, about \$8 in 1915, and as high as \$20 in July, 1918. The specimen variety sells for considerably less, and material for standardization sells for from \$1 to \$2 a pound.

The following firms are buyers of Iceland spar suitable for optical use: Bausch & Lomb Optical Co., Purchasing Department, Rochester, New York; Central Scientific Co., 460 Ohio Street east, Chicago, Illinois; Gilbert S. Day, Superintendent Optical Department, Eastman Kodak Co., Rochester, New York.

The market for specimen spar is irregular, as the demand is usually very light. The best market will probably be found with some of the larger mineral dealers.

Standardization material may be sold to large dealers in general chemicals as well as to mineral dealers.

Optical fluorite must yield or contain pieces at least one-fourth of an inch in diameter, which must be clear and colorless and free from all defects. Defects consist of internal cracks or cleavage planes, bubbles, or inclusions of dirt or mineral matter. The presence of faintly developed or incipient cleavage planes or fracture surfaces usually may be determined, if not readily visible, by moistening the specimen with kerosene. The material must not show any anomalous double refraction. Absolutely clear-water material is of the highest value, but very faint tints of green, yellow, or purple do not render the material useless.¹

Suitable material has been obtained from several of the fluorite mines in Hardin County, Illinois, and may also occur in the extension of this fluorite belt in western Kentucky. Although fluorite is found in many other States, practically none of them is known to contain any "optical fluorite."

Quartz.—See Rock crystal.

Rock crystal.—The perfectly clear and colorless variety of quartz is called rock crystal.

It furnishes the material for certain special glasses and fused silica ware; and it is used in wedges for microscopic work, as spectrographic prisms for special researches and as mechanical bearings. A use in connection with certain sounding boxes has recently been developed.

Sepiolite.—See Meerschaum.

Sapphire.—The variety of gem corundum used for other purposes than jewelry is called sapphire, irrespective of its color. It is used for mechanical bearings and pivot supports, especially in watches and phonograph needles (mostly artificial sapphire).

Topaz.—Abrasive.

Tourmaline.—In the tourmaline tongs or in polarizing forceps, a very simple form of polariscope.

Fluorite suitable for optical use is valued at from \$1 to \$10 a pound, according to the size of the piece suitable for cutting as well as to its quality. The present yearly requirement is not large—perhaps several hundred pounds—but under proper conditions and with a dependable steady supply this requirement may be increased.

Possible buyers of optical fluorite are: Bausch & Lomb Optical Co., Rochester, New York; Spencer Lens Co., Buffalo, New York; Ward's Natural Science Establishment, Rochester, New York; United States Bureau of Standards, Washington, District of Columbia.

APPENDIX 6.

TABLES FOR THE IDENTIFICATION OF PRECIOUS STONES.

The accurate identification of a precious stone, even by an expert, is often a matter of considerable difficulty, and, indeed, sometimes rendered quite impossible by the manner in which the stone is mounted. The task, as a rule, is quite beyond the skill of the untrained. The method given below has been prepared by Dr. Edgar T. Wherry, formerly in charge of the Division of Mineralogy. The appliances needed comprise:

Sharp-pointed fragments of the minerals diamond, corundum, and quartz, preferably set in wooden handles the size of ordinary lead pencils.

Cleavage pieces or crystals, with good bright surfaces, of the minerals corundum, quartz, and feldspar (microcline).

Some means for determining specific gravity, such as picnometer, fine platinum-wire cage to be hung on chemical balance, small Nicholson hydrometer, etc. Liquids with high specific gravities, upon which stones of lower gravity will float, such as methylene iodide, specific gravity 3.30; acetylene tetrabromide, specific gravity 2.95; and bromoform, specific gravity 2.85, are also useful.

A microscope provided with nicol prisms, and a small, round-bottomed glass dish to be placed in the center of its stage, in which the stone can be immersed in a high-refracting liquid such as α -mono-brom-naphthalene, $n = 1.66$.

The stone is:

I. Colorless, white, or very pale tinted.

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum point.

1. Scratches corundum surface; not scratched by diamond point....Diamond.
2. Does not scratch corundum surface.....Corundum (white sapphire).

(b) Hardness 8 to 7; scratched by corundum, but not by quartz.

1. Specific gravity very high, 4.5.....Zircon.
2. Specific gravity high, 3.5.....Topaz.
3. Specific gravity medium, 2.65.....Quartz (rock crystal).

(Colorless varieties of beryl, chrysoberyl, garnet, spinel, spodumene, and tourmaline, and the rare minerals danburite and phenakite, belong here.)

(c) Hardness less than 7; scratched by quartz.

1. Isotropic between crossed nicols under the microscope....Glass (artificial).
2. Anisotropic.....Feldspar (varieties).

(The rare minerals beryllonite and datolite belong here.)

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

1. Luster waxy; not scratched by quartz.....Chalcedony.
 2. Luster greasy; scratched by quartz.....Jade.
- (Compact white vesuvianite (californite) belongs here.)

(b) Hardness less than 6; do not scratch microcline.

(White agalmatolite, serpentine, opal, and opaque glass belong here.)

II. Color violet, red-violet, and related hues.

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum.

1. Does not scratch corundum surface.....Corundum (oriental amethyst).
(The rare violet-colored diamond belongs here; it scratches corundum.)

(b) Hardness 8 to 7; scratched by corundum, but not by quartz.

1. Specific gravity very high, 4.....Garnet (almandine and rhodolite).
2. Specific gravity high, 3.6.....Spinel.
3. Specific gravity rather high, 3.2.....Spodumene (kunzite).
4. Specific gravity medium, 2.65.....Quartz, amethyst.
(The rare violet-colored varieties of iolite, tourmaline, and zircon, and the rare mineral axinite, belong here.)

(c) Hardness less than 7; scratched by quartz.

1. Isotropic.....Glass (artificial).
(The rarely used violet varieties of apatite belong here.)

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

(The rare violet chalcedony and the rare mineral dumortierite belong here.)

(b) Hardness less than 6; do not scratch microcline.

(The rarely used lepidolite, pyroxene variety violan, and opaque violet glass belong here.)

III. Color blue and related hues.

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum.

1. Does not scratch corundum surface.....Corundum, sapphire.
(The rare blue-colored diamond belongs here; it scratches corundum.)

(b) Hardness 7; scratched by corundum, but not by quartz.

1. Sp. gr. 4.6; color pale blue, essential.....Zircon.
2. Sp. gr. 3.6; color deep green-blue, essential.....Spinel.
3. Sp. gr. 3.5; color pale blue, disperse.....Topaz.
4. Sp. gr. 3.1; color deep smoky or green-blue, essential. Tourmaline (indicolite).
5. Sp. gr. 2.7; color pale blue or green-blue, disperse.....Beryl, aquamarine.
6. Sp. gr. 2.6; pleochroic, blue to yellow.....Iolite.
(The rare mineral euclase belongs here.)

(c) Hardness less than 7; scratched by quartz.

1. Isotropic.....Glass.
(The rare blue-colored varieties of apatite, fluorite, kyanite, and opal, and the rare minerals benitoite and hauynite, belong here.)

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

1. Luster waxy (in part artificially colored by dyes).....Chalcedony.
2. Luster glassy; color due to inclusions.....Quartz.

(b) Hardness 6 or less; do not scratch microcline.

1. Sp. gr. 3.8; color deep blue; effervesces with acid.....Azurite.
2. Sp. gr. 2.8; color pale green-blue; luster waxy.....Turquoise.
3. Sp. gr. 2.4; color mottled and showing pyrite dots.....Lapis-lazuli.
(Several little-used minerals belong here, such as calamine (copper-stained), chrysocolla, crocidolite, smithsonite (copper-stained), sodalite, etc.; also glass imitations of turquoise.)

IV. Color green.

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum.

1. Does not scratch corundum surface.....Corundum, oriental emerald.
(The rare green-colored diamond belongs here; it scratches corundum.)

IV. Color green—Continued.

A. Transparent or nearly so—Continued.

(b) Hardness 8 to 7; scratched by corundum but not by quartz.

1. Sp. gr. 3.7; color yellow-green, in artificial light red. Chrysoberyl, alexandrite.
2. Sp. gr. 3.2; color pale brown-green or yellow-green.....Andalusite.
3. Sp. gr. 3.1; pleochroic, pale to deep green.....Tourmaline.
4. Sp. gr. 2.7; color pale blue-green, faintly pleochroic.....Beryl.
5. Sp. gr. 2.7; color deep green, moderately pleochroic.....Beryl, emerald.
6. Sp. gr. 2.65; color pale, cloudy green. not pleochroic.....Quartz, prase.

(The rare green-colored varieties of euclase, topaz, and zircon belong here.)

(c) Hardness less than 7; scratched by quartz.

1. Sp. gr. 3.8; color deep yellow-green; isotropic.....Garnet, demantoid.
2. Sp. gr. 3.5; pleochroic, deep green-yellow to brown.....Epidote.
3. Sp. gr. 3.4; pleochroic, yellow-green to green-yellow.....Titanite, sphene.
4. Sp. gr. 3.4; faintly pleochroic; color green-yellow.....Chrysolite, peridot.
5. Sp. gr. 3.3; not pleochroic; color pale green.....Pyroxene, diopside.
6. Sp. gr. 3.2; pleochroic, pale to deep green.....Spodumene, hiddenite.
7. Sp. gr. 2.5; color dark brown-green; isotropic.....Obsidian, moldavite.
8. Sp. gr. mostly below 3; isotropic.....Glass (artificial).

(The rarely used minerals diopase and prehnite and the rare green-colored varieties of apatite, enstatite, fluorite, and vesuvianite belong here.)

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

1. Sp. gr. 3.3; luster rather vitreous; color yellow-green.
Vesuvianite, californite.
2. Sp. gr. 3.3; luster rather greasy; color green or greenish gray..Jade (jadeite).
3. Sp. gr. 2.6; luster rather waxy; color pale blue-green.
Chalcedony, chrysoprase.
4. Sp. gr. 2.6; luster rather dull; color dark blue-green...Chalcedony, plasma.

(When plasma is spotted with red it is known as bloodstone.)

(b) Hardness 6 or less; do not scratch microcline.

1. Sp. gr. 4; color intense green; luster rather silky.....Malachite.
2. Sp. gr. 3, color green or greenish gray; luster greasy.....Jade (nephrite).
3. Sp. gr. 2.8; color pale blue-green; luster rather waxy.....Turquoise.
4. Sp. gr. 2.6; color pale or deep green; luster greasy.....Serpentine.
5. Sp. gr. 2.6; color blue-green, streaky; luster vitreous.
Microcline, amazonstone.
6. Sp. gr. 2.6; color green-blue-green; luster waxy.....Variscite.
7. Sp. gr. mostly below 3; isotropic; luster vitreous.....Glass (artificial).

(Several little-used minerals belong here, such as calamine (copper-stained), chlorastrolite, chrysocolla, fuchsite, smithsonite (copper-stained), etc.)

V. Color yellow.

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum.

1. Scratches corundum surface; not scratched by diamond point...Diamond.
2. Does not scratch corundum surface.....Corundum (oriental topaz).

(b) Hardness 8 to 7; scratched by corundum but not by quartz.

1. Sp. gr. very high, 4.5.....Zircon, hyacinth.
2. Sp. gr. high, 3.7.....Chrysoberyl.
3. Sp. gr. fairly high, 3.5.....Topaz.
4. Sp. gr. medium, 2.7.....Beryl, golden.
5. Sp. gr. 2.65.....Quartz, citrine.

(The rare yellow varieties of chrysolite, danburite, garnet, spinel, and tourmaline belong here.)

V. Color yellow—Continued.

A. Transparent or nearly so—Continued.

(c) Hardness less than 7; scratched by quartz.

1. Sp. gr. fairly high, 3.4; pleochroism distinct.....Titanite, sphene.

2. Sp. gr. mostly less than 3; isotropic.....Glass (artificial).

3. Sp. gr. very low, 1.1.....Amber.

(The rarely used yellow forms of apatite, chrysolite, fluorite, microlite, sphalerite, spodumene, vesuvianite, and willemite belong here.)

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

1. Sp. gr. medium, 2.6 (in part artificially colored).....Chalcedony.

2. Like preceding, but more opaque.....Chalcedony, jasper.

3. Luster silky.....Quartz after crocidolite.

(b) Hardness less than 6; do not scratch microcline.

1. Sp. gr. mostly below 3; luster glassy.....Glass (artificial).

(The rare yellow varieties of serpentine and smithsonite, and the little used mineral cancrinite belong here.)

VI. Color brown (including orange-color).

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum.

(The rare brown-colored diamond belongs here.)

(b) Hardness 8 to 7; scratched by corundum but not by quartz.

1. Sp. gr. high, 4.5; double refraction strong, very brilliant.....Zircon.

2. Sp. gr. high, 4.1; isotropic.....Garnet, essonite, spessartite.

3. Sp. gr. fairly high, 3.....Tourmaline.

4. Sp. gr. medium, 2.7.....Quartz, smoky.

(The rarely used mineral staurolite, and the rare brown-colored varieties of andalusite, chrysoberyl, spinel, and topaz belong here.)

(c) Hardness less than 7; scratched by quartz.

1. Sp. gr. fairly high, 3.4; pleochroism distinct.....Titanite.

2. Sp. gr. medium, mostly less than 3; isotropic.....Glass (artificial).

3. Sp. gr. very low, 1.1.....Amber.

(The rarely used minerals axinite, epidote, fluorite, chondrodite, sphalerite, staurolite, and vesuvianite belong here.)

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

1. Sp. gr. high, 3.7; color deep brown.....Staurolite.

2. Sp. gr. medium, 2.6; in part artificially colored.....Chalcedony.

3. Same, banded.....Chalcedony, agate.

4. Same, but more opaque.....Chalcedony, jasper.

5. Same, but luster highly silky.....Quartz after crocidolite.

(b) Hardness less than 6; do not scratch microcline.

1. Sp. gr. medium, 2.6.....Obsidian.

2. Sp. gr. mostly less than 3.....Glass (artificial).

(Some rarely-used varieties of feldspar and altered staurolite belong here.)

VII. Color red or pink.

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum.

1. Does not scratch corundum surface.....Corundum, ruby.

(The rare pink colored-diamond belongs here; it scratches corundum.)

VII. Color red or pink—Continued.

A. Transparent or nearly so—Continued.

(b) Hardness 8 to 7; scratched by corundum but not by quartz.

1. Sp. gr. high, 3.9; color intense red; isotropic.....Garnet, pyrope, (etc.).
2. Sp. gr. fairly high, 3.6; color intense red; isotropic.....Spinel, balas-ruby.
3. Sp. gr. fairly high, 3.5; color orange-red to pink; anisotropic.....Topaz.
4. Sp. gr. fairly high, 3.1, color pink; pleochroism strong..Tourmaline, rubellite.
5. Sp. gr. medium, 2.7; color pink; pleochroism faint....Beryl, "morganite."
(The rare pink grossularite garnet and the red variety of zircon belong here.)

(c) Hardness less than 7; scratched by quartz.

(The little used mineral piedmontite, and the rare red-colored varieties of amber, and pink-colored varieties of fluorite and spodumene-kunzite belong here; also opal and artificial glass.)

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

1. Sp. gr. fairly high, 3.3; color dull red or violet red.....Zoisite, thulite.
2. Sp. gr. medium, 2.6; color pink, cloudy.....Quartz, rose.
3. Same, but color red.....Chalcedony, carnelian.
4. Same, but more opaque.....Chalcedony, jasper.
5. Same, but banded.....Chalcedony, agate.

(b) Hardness less than 6; will not scratch microcline.

(The little used minerals lepidolite, rhodonite, and rutile belong here; also coral and artificial glasses.)

VIII. Color black.

(a) Hardness 9 or greater; not scratched by corundum.

(Black diamond or carbonado belongs here; it scratches corundum.)

(b) Hardness 8 to 7; scratched by corundum but not by quartz.

1. Sp. gr. 2.7.....Quartz, smoky.
2. Same, more opaque; artificially colored.....Chalcedony.
3. Same, banded.....Chalcedony, agate.
(The rarely used black varieties of spinel and tourmaline belong here.)

(c) Hardness less than 7; scratched by quartz.

1. Sp. gr. very high, 5.3; "streak" (powder) red.....Hematite.
2. Sp. gr. medium, 2.5; glassy.....Obsidian.
3. Sp. gr. medium; glassy.....Glass (artificial).
4. Sp. gr. low.....Jet (and coal).

(The little used minerals allanite, chromite, gadolinite, ilmenite, magnetite, rutile, and samarskite belong here.)

Possessing internal colors:

A. Transparent or nearly so.

(a) Hardness 9 or greater; not scratched by corundum.

1. Does not scratch corundum surface; int. refl. silvery, 6-rayed.

Corundum, asteria.

(b) Hardness 8 to 7; scratched by corundum but not by quartz.

1. Sp. gr. 2.7; int. refl. silky, forming fine sharp line...Chrysoberyl, cat's-eye.
2. Sp. gr. 2.7; int. refl. silky, forming broad band.....Quartz, cat's-eye.
(The rare tourmaline-cat's-eye belongs here.)

(c) Hardness less than 7; scratched by quartz.

1. Sp. gr. medium, 2.6; int. refl. blue to silvery-white...Feldspar, moonstone.
2. Sp. gr. rather low, 2.2; int. refl. various brilliant colors.....Opal.
(Some amber, feldspar variety sunstone, obsidian, and various kinds of artificial glass belong here.)

Possessing internal colors—Continued.

B. Opaque or nearly so.

(a) Hardness greater than 6; scratch microcline.

1. (Some asteria corundum is practically opaque; see A. a 1.)

Corundum, asteria.

2. Int. refl. silky, forming broad band; color brown-yellow... Quartz, tiger-eye.

3. Int. refl. silky, forming broad band; color gray, green, etc.. Quartz, cat's-eye.

4. Int. refl. spangled; color various..... Quartz, aventurine.

(b) Hardness 6 or less; do not scratch microcline.

1. Sp. gr. 3.4; int. refl. bronzy; color dark brown.

Hypersthene (including bronzite).

2. Sp. gr. 2.7; shows pearly luster and delicate color-play..... Calcite, pearl.

3. Sp. gr. 2.7; color gray; int. refl. blue, green, red, etc.. Feldspar, labradorite.

4. Sp. gr. 2.7; color gray; int. refl. red, spangled..... Feldspar, sunstone.

5. Sp. gr. 2.5; color dull green; int. refl. silky, gray..... Serpentine, satellite.

6. Sp. gr. 2.3; very soft, color white; int. refl. strongly silky.

Gypsum, satin-spar.

APPENDIX 7.

STATISTICS OF PRODUCTION.¹

Value of precious stones produced in the United States, 1913-1919.

	1913	1914	1915	1916	1917	1918	1919
Beryl.....	\$1,615	\$2,395	\$1,675	\$2,031	\$2,178	\$1,906	(a)
Copper-ore gems.....	2,350	1,280	1,120	1,713	2,857	2,299	(a)
Corundum.....	238,835	61,032	88,214	99,180	54,204	42,414	\$40,304
Diamond.....	6,315	765	608	2,680	4,175	1,910	(a)
Feldspar.....	1,285	449	368	305	(b)	(b)	(b)
Garnet.....	4,285	1,760	4,523	1,542	624	1,277	1,630
Hematite.....			126	(b)	(b)	138	(b)
Jade.....		300					
Opal.....	15,130	1,114	1,850	1,838	805	6,304	(a)
Peridot.....	375	100	(b)	455	(b)	1,018	
Pyrite.....	50		1,042	2,075	(b)	(b)	
Quartz.....	16,861	18,838	35,724	25,707	28,273	15,211	17,632
Rhodonite.....	165	1,050	85	(b)	(b)	515	160
Smithsonite.....	50	50	(b)		(b)		
Spodumene.....	6,520	4,000	(b)	(b)	(b)	281	
Thomsonite.....		21	(b)	47	(b)	(b)	(b)
Topaz.....	736	1,380	862	1,005	230	907	210
Tourmaline.....	7,630	7,980	10,969	50,807	12,452	6,206	17,700
Turquoise.....	8,075	13,370	11,691	21,811	14,171	20,667	22,750
Variscite.....	6,105	5,055	3,867	3,140	2,350	753	925
Vesuvianite.....	152	1,425	1,535	(c)	2,765	320	
Beryl, copper-ore gems, dia- mond, opal.....	(c)	(c)	(c)	(c)	(c)	(c)	8,832
Miscellaneous gems.....	2,920	2,287	d 6,172	e 3,457	f 5,928	g 4,397	h 1,620
	319,454	124,651	170,431	217,793	131,012	106,523	111,763

^a Less than 3 producers; figures combined with others to avoid disclosing confidential information.

^b Small production included under "Miscellaneous gems."

^c For value of production in this year, see above.

^d Includes apatite, calamine, chlorastrolite, crocidolite, datolite, fossil coral, Iceland spar, kyanite, lapis lazuli, obsidian, peridot, phenacite, rutile, smithsonite, spodumene (kunzite), staurolite, thomsonite, titanite, and zircon.

^e Includes chlorastrolite, datolite, epidote, fossil coral, hematite, kyanite, lazulite, rhodonite, rutile, sepiolite, serpentine, spodumene, staurolite, and vesuvianite.

^f Includes andalusite, chlorastrolite, datolite, epidote, feldspar, fossil coral, hematite, Iceland spar, lapis lazuli, obsidian, peridot, phenacite, pyrite, rhodonite, rutile, sepiolite, smithsonite, spodumene, staurolite, thomsonite, willemite, and zoisite.

^g Includes andalusite, calamine, chlorastrolite, datolite, epidote, feldspar, fluorite, Iceland spar, lapis lazuli, mariposite, meerschau, obsidian, phenacite, pyrite, satin spar (gypsum), staurolite, thomsonite, willemite, and zoisite.

^h Includes chlorastrolite, datolite, feldspar, fossil coral, hematite, jet, lapis lazuli, meerschau, spinel, spodumene (kunzite), thomsonite, and Iceland spar.

¹ From Mineral Resources of the United States, 1919. Pt. 2, 1921.

APPENDIX 8.

SELECTED BIBLIOGRAPHY.

The very full bibliographies given in Tagore's "Mani-Málá," Feuchtwänger's "Treatise on Gems," Wodiska's "Book of Precious Stones," and Pogue's "The Turquoise" seemingly render unnecessary a reference here to any but a few of the more general treatises.

- BAUER, MAX. *Edelsteinkunde.*
 Leipzig, 1896.
 English translation by L. J. Spencer. Lippincott & Co., Philadelphia.
- BOUTAN, M. E. *Le diamant.*
 Paris, 1886.
 Contains a very full bibliography up to date of issue.
- BURNHAM, S. M. *Precious stones in nature, art, and literature.*
 Boston, 1886.
- CATTELLE, W. R. *Precious stones. A book of reference for jewelers.*
 Philadelphia and London, 1903.
- CHURCH, A. H. *Precious stones, considered in their scientific and artistic relations.*
 London, 1882.
- CLAREMONT, L. *Precious stones.*
 Philadelphia and London. J. B. Lippincott Co., 1903, 224 pp., xix plates, 8°.
- DIEULAFAIT, L. *Diamonds and precious stones; a popular account of gems.*
 New York, 1874.
- DOELTER, C. *Edelsteinkunde. Bestimmung und Untersuchung der Edelsteine und Schmucksteine; Kuenstliche Darstellung der Edelsteine.*
 Leipzig, 1893.
- EMANUEL, H. *Diamonds and precious stones.*
 London, 1865.
 Contains a very full bibliography to date of publication.
- ESCARD, J. *Les pierres precieuses (precious stones), 520 pp., illustrated with colored plates.*
 Paris, H. Dunod et E. Pinat, 1914. (About \$7.)
- FARRINGTON, O. C. *Gems and minerals. 229 pp., illustrated with colored plates.*
 Chicago, A. W. Mumford Co., 1903. (\$3.)
- FEUCHTWÄNGER, L. *A popular treatise on gems in reference to their scientific value.*
 New York, 1872.
- FURTWÄNGLER, A. *Die antiken Gemmen. Geschichte der Steinschneidekunst im klassischen Altertum.*
 Leipzig, Berlin: Gieseck and Devrient, 1900. 3 vols, illustrations, plates.
- GOODCHILD, W. *Precious stones. 309 pp., illustrated. Archibald Constable and Co. Ltd. (\$2.)*
 London, 1908.
- HAMLIN, A. C. *The tourmaline.*
 Boston, 1873.
- HINDMARSH, R. *Precious stones,, being an account of the stones mentioned in the Sacred Scriptures.*
 London, 1851.
- JANETTAZ, N. and E. FONTENAY, EM. VANDERHEGEN, and A. COUTANCE. *Diamant et pierres precieuses.*
 Paris, 1880.

- JAZEK, BOH. Aus dem Reiche der Edelsteine (In the domain of the precious stones), 171 pp., 8 pls., figs.
Prague, Austria, E. Weinfurter.
- KING, C. W. The natural history of gems or decorative stones.
London, 1867.
- KUNZ, GEORGE F. Gems, jewelers' materials, and ornamental stones of California, 2d ed.: California Min. Bureau, Bull. 37, 171 pp., illustrated (4 colored plates), 1905. (Price and postage, 58 cents.)
- The curious lore of precious stones, 406 pp., 61 pls. (6 in color), figs.
Philadelphia, J. B. Lippincott Co., 1913. (\$5.)
- Gems and precious stones of North America, 367 pp., illustrated with colored plates.
New York, Scientific Publishing Co., 1890. (\$10.)
- (CHARLES H. STEVENSON). The Book of the Pearl.
New York City, 1908, The Century Co.
- The fresh-water pearls and pearl fisheries of the United States. (In Bulletin of the United States Fish Commission, 1897, p. 375.)
- LIESEGANG, R. E. Die Achate (Agates), 118 pp., illustrated.
Dresden and Leipzig, 1915.
- LOWN, CLARENCE, and BOOTH, HENRY. Fossil Resins, a compilation.
New York, 1891, N. D. C. Hodges.
- MAWE, JOHN. A treatise on diamonds and precious stones, including their history, natural and commercial. To which is added some account of the best method of cutting and polishing them.
London, 1813.
- POGUE, J. E. The Turquoise: A study of its history, mineralogy, geology, ethnology, archeology, mythology, folklore, and technology. Nat. Acad. Sci., Mem., vol. 12, pt. 2, No. 3, 206 pp., 22 pls. (1 colored), figs., 1915.
Contains full bibliography to date.
- ROSENMÜLLER, E. F. C. Mineralogy of the Bible. Translated by Repp and Morren.
Edinburgh, 1840.
- ROTHSCHILD, M. D. Handbook of precious stones.
New York, 1890.
- SMITH, G. F. H. Gem stones and their distinctive characters. 312 pp., illustrated with colored plates.
London, 1912, Methuen and Co. Ltd. (\$2.10.)
- SCHALLER, W. T. The production of precious stones. Mineral Resources of the United States, 1915-1919.
- STERRETT, D. B. The production of precious stones.
Washington, D. C., 1907. Mineral Resources of the United States, 1906-1914.
- STREETER, E. W. Precious stones and gems.
London, 1877.
- Great diamonds of the world.
London, 1892.
- TAGORE, S. M. Mani-Málá, a treatise on gems. 2 vols.
Calcutta, 1879.
Contains a bibliography of Sanskrit, Persian, Arabic, and other oriental works on gems.
- WILLIAMS, G. F. The diamond mines of South Africa. 2 vols., 359 and 353 pp., illustrated.
New York, B. F. Buck and Co., 1905.
- WODISKA, JULIUS. A book of precious stones. 363 pp., illustrated with colored plates.
New York, 1910, G. P. Putnam's Sons.

INDEX.

This index is restricted to the gem and mineral names used in this bulletin.

	Page.		Page.
Achirite.....	179	Amethyst.....	86, 123, 125, 148, 156, 180
Achroite.....	179	burnt.....	182
Actinolite.....	179	false.....	186
Adamantine spar.....	179	Occidental.....	191
Adularia.....	50, 179	Oriental.....	192
Aeroides.....	179	Siberian.....	196
Agalmatolite.....	127, 179	Amphibole.....	180, 199
Agate.....	22, 129, 148, 154, 179, 205	Anatase.....	180
blood.....	181	Andalusite.....	10, 180, 199
coral.....	184	Audesine.....	180
dendritic.....	185	Andradite.....	180
eye.....	186	Anhydrite.....	199
fortification.....	186	Ankerite.....	199
glass.....	187	Anthracite.....	180
green.....	187	Apatite.....	180, 199
Iceland.....	188	Aphrizite.....	180
Indian.....	188	Apophyllite.....	180, 199
jasp.....	189	Apricotine.....	180
mocha.....	190	Aquamarine.....	14, 122, 125, 180
Montana.....	191	Brazilian.....	182
mosaic.....	191	Oriental.....	192
moss.....	26, 121, 122, 126, 129, 191	Siberian.....	196
Occidental.....	191	Aragonite.....	19, 131, 180, 199
Oriental.....	192	Arkansite.....	180
opal.....	192	Armenian stone.....	180
Petosky.....	193	Arrow points.....	181
rainbow.....	194	Asparagus stone.....	181
riband.....	194	Asteria.....	181
ring.....	194	Automolite.....	181
river.....	194	Aventurine.....	181
Texas.....	197	Axinite.....	11, 181
tree.....	197	Axstone.....	181
water.....	198	Aztec stone.....	181
wax.....	198	Azulite.....	181
wood.....	198	Azure stone.....	181
Agate jasper.....	180	Azurite.....	11, 70, 181, 190, 205
Agrite.....	180	Azurite malachite.....	181
Alabaster.....	155, 180	Azurmalachite.....	181, 205
Oriental.....	192	Bahias.....	181
Alalite.....	180	Barite.....	181
Albite.....	51, 180	Basanite.....	181
Aleppo stone.....	180	Bastite.....	181
Alexandrite.....	30, 180	Beckite.....	181
Allanite.....	180	Beckite.....	181
Almandite.....	56, 123, 180	Bemescite.....	181
Amatrice.....	125, 180	Benitoite.....	12, 122, 181
Amazonstone.....	50, 123, 128, 180	Beryl.....	12, 122, 148, 156, 181, 199
Amber.....	9, 148, 155, 180	caesium.....	13, 182
black.....	181	canary.....	183
Amberine.....	180	common.....	13
Ambroid.....	180	golden.....	13, 187
Amethyste basaltine.....	180	Beryllonite.....	17, 181
