Abstract.—Two cosmopolitan species of frigate tunas, *Auxis thazard* (Lacepède) and *A. rochei* (Risso), are differentiated primarily by the width of the corselet under the origin of the second dorsal fin and by the anterior extent of the dorsal scaleless area above the pectoral fin. *Auxis thazard* has five or fewer scales in the corselet under the second dorsal fin, and the dorsal scaleless area extends anterior to the tip of the pectoral fin; *A. rochei* has six or more scales and the dorsal scaleless area does not reach the tip of the pectoral fin. Of nine morphometric characters examined with ANCOVA, four body depth measurements were significantly different between the species. *Auxis rochei* is a slender species with a deeper, more robust body and with more unequal body depth measurements. For both species, eastern Pacific populations differ from Atlantic and Indo-West Pacific populations at what we consider the subspecific level. The eastern Pacific *A. thazard brachydorax* new subspecies has more gill rakers, usually 43–48 vs. usually 38–42 in *A. t. thazard*. Body depth at anal-fin origin, pectoral-fin length, and corselet width were also significantly different between *A. thazard brachydorax* and *A. t. thazard*. The eastern Pacific *A. rochei eudorax* new subspecies has an even wider corselet than that of *A. rochei rochei*, usually more than 20 scales wide compared with 6–19 scales.

Revision of the frigate tunas *(Scombridae, Auxis)*, with descriptions of two new subspecies from the eastern Pacific

It is not clear whether there are one or two species of frigate tunas of the genus *Auxis*. In the Indo-West Pacific region, several investigators have distinguished a narrow-corseleted species (N) from a wide-corseleted species (W): Bleeker (1854, 1855) from the East Indies as *A. tapeinosoma* (N) and *A. thynnoides* (W); Kishinouye (1915, 1923) from Japan as *A. hira* (N) and *A. maru* (W); Wade (1949) from the Philippines and Jones (1958) from India as *A. thazard* (N) and *A. tapeinosoma* (W); and Matsumoto (1960a) from Hawaii as *A. thazard* (N) and *A. thynnoides* (W). However, most Atlantic-based workers have considered the frigate tunas to be a single worldwide species which they have identified as *Auxis thazard* (Dresslar and Fesler, 1889; Jordan and Evermann, 1896; Fraser-Brunner, 1950; Rivas, 1951; Zavala-Camin, 1983). Fitch and Roedel (1963) have shown that there are two sympatric species of frigate tunas in the Indo-West Pacific: the narrow-corseleted *A. thazard* (Lacepède) and the wide-corseleted *A. rochei* (Risso) (Fig. 1). They used the name *A. rochei* for the wide-corseleted species on the supposition that only one species occurred in the Mediterranean Sea and Atlantic Ocean and that *rochei* was the earliest name for it. Richards and Randall (1967) have shown that both species occur in the Atlantic, reopening the question of the proper name for Atlantic *Auxis*.

Frigate tunas (*Auxis*) are the smallest members of the tribe Thunnini, the true tunas. *Auxis rochei* reaches a fork length (FL) of 600 mm and *Auxis thazard*, at least 420 mm. To date, frigate tunas have not been greatly exploited, partly because of their small size. Of the total world catch of tunas, bonitos, and billfishes in 1993 (4,654,750 metric tons (t), FAO, 1995), only 4.5% (208,305 t) was *Auxis*. The largest landings are by Asian countries (Philippines 110,357 t; Thailand 36,300 t; Japan 27,896 t; and India 15,684 t). *Auxis* has soft meat and is not suitable for sashimi (slices of raw fish) because of its strong astringent taste, probably due to the high level of free amino acids in the meat (Murata et al., 1994). At least as larvae, *Auxis* are widespread and very abundant (Yabe et al., 1963, fig. 15; Ahlstrom, 1971; Ramiriz-Estevez and Ornelas-
Roa, 1991). Richards (1984:28) concluded that *Auxis* "... is the most widely distributed and abundant scombrid in tropical seas." With stocks of other tuna species continually diminishing, there is increased potential for greater exploitation of *Auxis*. Before exploitation increases, it is necessary to establish how many species exist and what their correct names are, to determine how to identify them, and to obtain some idea of the major worldwide populations.

Fitch and Roedel (1963) also showed that the eastern Pacific populations of both species differed significantly from the Indo-West Pacific populations but did not name them pending further work. We confirm Fitch and Roedel's findings that the eastern Pacific population of *A. thazard* has more gill rakers (usually 43–48) than other populations (usually 38–42 in Atlantic and Indo-West Pacific populations), similar to the counts for *A. rochei*. The eastern Pacific population of *A. rochei* has an even wider corselet (usually more than 20 scales wide under the second dorsal fin) than other populations (8–19 scales in populations from the Indo-West Pacific).

This paper distinguishes the two species. We have located the type specimen of *rochei* and designate a neotype for *thazard* to stabilize current use of these names for these species. We evaluate the systematic status of eastern Pacific populations of the two species and describe them as new subspecies, *Auxis thazard brachydorax* and *Auxis rochei eudorax*.

### Materials and methods

Methods follow those used by Collette and Gillis (1992), in a revision of the double-lined mackerels *Grammatorcynus*, and by Collette and Russo (1985) in a revision of the Spanish mackerels *Scomberomorus*. Morphometric characters used in this study are as follows: FL (fork length); HdL (head length); P1L (pectoral-fin length); P1T (distance from pectoral-fin tip to anterior edge of dorsal scaleless area above lateral line); and CW (corselet width under second dorsal-fin origin). Owing to the different shapes of *A. rochei* and *A. thazard*, we postulated that four body depth measurements would illustrate these differences: 1Dor (body depth at origin of first dorsal); 1Dend (body depth at posterior end of first dorsal); 2Dor (body depth at origin of second dorsal); and Aor (body depth at anal-fin origin). *Auxis rochei* is a more slender species and the four body depth
measurements are approximately equal, whereas *A. thazard* is more tuna-shaped, having narrow entering and departing wedges and more unequal body depths.

Morphometric data were analyzed with regression analysis, analysis of covariance (ANCOVA), and principal component analysis (PCA). Regression analysis was run on the combined morphometric data for all populations of *A. rochei* vs. the combined populations of *A. thazard* to determine whether morphometric differences exist between species. Regression analyses were also run on morphometric data for major populations of each species to look for intraspecific differences. The following combinations of geographic populations were tested: for *A. rochei*—western Atlantic (n=36) vs. Mediterranean (n=34) plus eastern Atlantic (n=64), western Pacific (n=82) vs. eastern Pacific (n=37); for *A. thazard*—Gulf of Guinea (n=20) vs. Indian Ocean (n=38), western Pacific (n=75) vs. central Pacific (n=17), and westcentral Pacific (n=92) vs. eastern Pacific (n=69).

PCA was performed with the character variables FL, 1Dor, 1Dend, 2Dor, and Aor to determine whether these characters supported species level separation of *A. rochei* from *A. thazard* and separation between the eastern Pacific population and the other populations for both species. Very little separation was observed with PCA because 97.9% of the variation is explained by principal component 1. This means that almost 98% of the variation can be explained by differences in size, whereas only a little more than 2% of the variation can be explained by character differences among the different populations.

ANCOVA was performed on the variables 1Dor, 1Dend, 2Dor, Aor, P1L, and CW with size (FL) as the covariate to determine whether these characters differentiated *A. rochei* from *A. thazard* and to see whether eastern Pacific populations of each species were different from other populations. ANCOVA showed that morphometric data for each species were the same for all populations, except for the eastern Pacific, and could be combined. For each species, the combined populations were run against the eastern Pacific population to test the level of differentiation of the eastern Pacific population. For *A. rochei*, the combined populations we tested against the eastern Pacific (n=30) were western Atlantic (n=36), Gulf of Guinea (n=64), Mediterranean (n=34), Indian Ocean (n=9), and western Pacific (n=82). For *A. thazard*, the combined populations we tested against the eastern Pacific (n=63) were Indian Ocean (n=38), western Pacific (n=71), central Pacific (n=17), and Australia (n=4).

Material examined is listed at the end of each subspecies account and includes 267 specimens of *A. thazard* and 291 specimens of *A. rochei*. Abbreviations of institutions housing the material examined follow Leviton et al. (1985). CMFRI is the Central Marine Fisheries Research Institute, Cochin, India. ZRC is the current institutional code for the Zoological Reference Collection at the National University of Singapore.

**Systematics**

*Auxis* Cuvier, 1829

*Auxis* Cuvier, 1829:199. Type-species: *Scomber rochei* Risso, 1810, by subsequent designation of Gill, 1862

**Diagnosis** (Modified from Collette, 1979.) *Auxis* lacks the prominent paired fronto-parietal fenestra in the top of the skull found in all the other tunas, tribe Thunnini (except *Allothunnus*). The dorsal and ventral branches of the cutaneous artery originate separately from the dorsal aorta in *Auxis* (Godsil, 1954); a common cutaneous artery divides into dorsal and ventral branches laterally from the dorsal aorta in the other Thunnini. The ventral branch is very poorly developed, less so than in other Thunnini. The dorsal cutaneous artery lies ventral to the corresponding vein in *Auxis*; it lies dorsal in *Euthynnus* (Godsil, 1954). The vertebral column differs from all other scombrids in having a long pedicel or epihemal process (1.5–2 times the centrum depth) that forces the dorsal aorta to run much further ventrally from the vertebral column than in other tunas. The interpelvic process is single and very long, equal to or longer than the pelvic fins themselves; it is shorter than the pelvic fins in all other Scombridae.

**Description** Body robust, elongate, and rounded. Teeth small and conical, in a single series. Two dorsal fins, the first with 10–12 spines, separated from the second by a long interspace (at least equal to length of first dorsal-fin base), the second fin followed by 8 finlets; pectoral fins short; anal fin followed by 7 finlets. Gill rakers 36–49. Body naked except for the corselet, which extends posteriorly along the lateral line past the origin of the second dorsal fin. In *A. thazard*, the extension is only 1–5 scales wide beneath the second dorsal fin, in *A. rochei* it is six scales or more. A strong central keel is present on each side of the caudal-fin base between two smaller keels. Vertebrae: 20 precaudal plus 19 caudal, total 39. Color: dorsum bluish, turning to deep purple or almost black on the head; belly white, usually without stripes or spots, occasionally black spots present on
belly between pectoral and pelvic fins as in *Euthynnus*; pectoral and pelvic fins purple, their inner sides black.

**Relationships** *Auxis* is related most closely to *Euthynnus* (Kishinouye, 1923; Collette, 1979, 1984; Finnerty and Block, 1995). It has been considered (Collette, 1979) to be the most primitive member (except for *Allothunnus*) of the Thunnini, the true tunas, because it lacks the frontoparietal fenestra present in *Euthynnus, Katsuwonus*, and *Thunnus*, because its subcutaneous circulatory system is more poorly developed than that of the more advanced tunas, and because *Auxis* shows no suturing of the first vertebra to the skull as is present in higher Thunnini. Tunas have a pair of lateral retia which serve the red muscle and act as heat exchangers enabling them to maintain body temperatures several degrees warmer than ambient water (3.5–9.5°C, mean 5.9°C, in the case of *Auxis*, Schaefer, 1985). In addition, *Auxis* and *Euthynnus* share a large central heat exchanger below the vertebral column in a series of enlarged haemal arches. *Auxis* is endothermic at sizes of 200 mm FL and larger (Dickson, 1994). The liver is similar to that in *Euthynnus* in having a very long right lobe running the length of the body cavity (Fig. 2). Prominent branches of the hepatic vein are present on the ventral surface of the liver lobes in both genera. *Auxis* differs from *Euthynnus* in having a greatly reduced left liver lobe; the left and middle lobes are of about equal length in *Euthynnus*. A swimbladder is present in larvae but degenerates by 20 mm as in *Euthynnus* and *Katsuwonus* (Richards and Dove, 1971).

**Osteological comparisons** Several authors (Kishinouye, 1923; Watanabe, 1962, 1964; Yoshida and Nakamura, 1965; Chi and Yang, 1972; Uchida, 1981; Zavala-Camin, 1983) have reported osteological differences between the species. Watanabe (1962, 1964) found that there were two types of *Auxis* based on long and short parapophyses. The differences were more prominent in specimens larger than 111 mm, especially on the 25th and 27th vertebrae. *Auxis thazard* had long free parapophyses, whereas *A. rochei* (as *A. tapeinosoma*) had short free parapophyses. In addition, in young *A. thazard* the first free parapophysis is developed mostly on the 23rd vertebra, and the first inferior foramen occurs on the 27th or 28th vertebra. In young *A. rochei*, however, the first free parapophysis is usually produced on the 21st or 22nd vertebra, and the first foramen occurs on the 29th or 30th vertebra. Other differences between the two species were the ratio of the caudal vertebral length to precaudal vertebral length and the ratio of body height at anal-fin origin to length from first dorsal to second dorsal origin. Yoshida and Nakamura (1965) found that in *A. thazard* the length of the anterior branch of the haemal process of the 24th to the 28th vertebra was longer and contacted the preceding arch. In *A. rochei* the anterior branches of the haemal processes were short, more fragile, and were never in contact with the preceding haemal arches. The angle between the temporal crests and a line parallel to the supraoccipital crest ranged from 0 to 2 degrees in *A. rochei* and from 3 to 7 degrees in *A. thazard*. In skulls of the same length, skulls of *A. thazard* were wider than those of *A. rochei*.

**Larval differences** In several geographic regions, workers have been able to divide their material of larval and juvenile *Auxis* into what appear to be two
species (Wade, 1949, Philippines; Matsumoto, 1959; Gorbunova, 1969, 1974, Indian and Pacific oceans; Zhao et al., 1982, and Sun et al., 1986, China; Richards, 1989, western central Atlantic). Juveniles have been successfully identified (e.g. Wade, 1949), but larvae are more difficult to identify to species because the corselet scales and gill rakers that distinguish the adults are not fully developed in the larvae. For brief length intervals, pigment characters are useful in distinguishing two types of larvae.

Gorbunova (1974) distinguished between larvae of the two species. *Auxis rochei* is characterized by a seemingly slower rate of development and a shallower body depth. The relative size of the eye is smaller and the pigmentation on the caudal peduncle is less intense. *Auxis thazard* is distinguished by a more rapid rate of development, a greater body depth, a shorter caudal portion of the body, and more intense body pigmentation. Richards (1989) emphasized the presence of pigment along the lateral line in the posterior part of the body in *A. rochei* and its absence in *A. thazard*.

Biochemical differences The first attempts to separate the two species of *Auxis* biochemically were by Matsumoto (1960b) who found that Hawaiian specimens could be distinguished in a one-dimensional chromatogram. Taniguchi and Nakamura (1970) examined muscle protein of *A. thazard* and *A. rochei* by the cellulose acetate electrophoretic method. They found five components in the electropherograms of both species, but some components were not common to both. Electrophoretic patterns of the two species were clearly distinguishable from each other by the mobility and percentage of each component. Taniguchi and Koniashi (1971) used starch gel electrophoresis to detect protein specificity between *A. thazard* and *A. rochei*. No individual variation occurred in the electropherograms of 11 specimens of *A. thazard*, whereas all 170 specimens of *A. rochei* fit into 1 of 3 phenotypic patterns. They hypothesized that these three phenotypes are controlled by two codominant alleles. Distribution of the three phenotypes was independent of age and sex.

**Auxis thazard** (Lacepède, 1800)

Frigate tuna

**Diagnosis** *Auxis thazard* has a narrow corselet that is 0.5–3.5 mm, usually 0.5–1.0 mm wide (Fig. 3) but no more than five scales wide under the second dorsal-fin origin (Table 1), a greater body depth at the anal-fin origin (Fig. 4), and the anterior margin of the scaleless area above the corselet extends anteriorly beyond the tip of the pectoral fins (Figs. 1 and 5) unlike that in *A. rochei*. Color pattern: 15 or more

| E. Pacific     |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

narrow, oblique to nearly horizontal, dark wavy lines in the scaleless area above the lateral line (Figs. 1 and 6). Spots sometimes occur between the pectoral and pelvic fins (see Robins and Ray, 1986: pl. 48), as they usually do in Euthynnus.

Geographical distribution Probably cosmopolitan in warm waters (Fig. 7) but there have been relatively few documented occurrences in the Atlantic Ocean. Although we did not examine specimens of either species from the southeastern Atlantic and although Zavalla-Camin (1983) concluded that there was only a single variable species, both species do occur there as can be seen from the anterior extent of the dorsal scaleless area (Fig. 8, 20 specimens of A. thazard and 33 specimens of A. rochei). On the basis of two specimens of A. thazard from Haifa, Israel (HUJ 17480, HUJ 17826) provided by Dani Golani, we believe both species occur in the Mediterranean Sea.

Habitat and biology From literature summarized in Uchida, 1981, and Collette and Nauen, 1983:29.) An epipelagic, neritic, and oceanic species. In the eastern Pacific, mature fish occur throughout the

Figure 8
Distance from the tip of the pectoral fin to the anterior extent of the dorsal scaleless area above the lateral line in *Auxis* from southeastern Brazil (from Zavala-Camin, 1983: fig. 4). The scaleless area extends 3–14 mm anterior to the tip of the pectoral fin in 20 specimens of *A. thazard* but falls short of the pectoral-fin tip or extends slightly anterior to it in 33 specimens of *A. rochei*.

year; although off Costa Rica spawning is heaviest from December through April, whereas in Japanese waters it peaks in July as expressed by the index of sexual maturity. In the southern Indian Ocean, the spawning season extends from August to April; north of the equator it is reported from January to April. Fecundity was estimated at about 1.37 million eggs per year in a 44.2-cm-long female. Fecundity of fish in Indian waters ranged between approximately 200,000 to 1.06 million eggs per spawning in correlation with size of females.

**Size** Maximum fork length from drift net records in the Indian Ocean is 510 mm, but off Sri Lanka it is 580 mm; common lengths range between 250 and 400 mm FL depending on gear type and may also vary seasonally and by region. Size at first maturity is reported at about 290 mm FL in Japanese waters but at about 350 mm around Hawaii. *Auxis thazard* grows to be larger than *A. rochei*.

**Subspecies** The eastern Pacific population of *A. thazard* has more gill rakers, leading us to describe it as a separate subspecies. Linear regression analyses of morphometric characters for *A. thazard* showed significant differences between the eastern Pacific and the remaining combined populations in four char-
acters: CW, P1L, 2Dor, and Aor. ANCOVA showed differences that were significant at the 0.01 level of significance for three morphometric characters: AOR, P1L, and CW, further supporting recognition of an eastern Pacific subspecies of *A. thazard*.

**Auxis thazard thazard** (Lacepède, 1800)

Fig. 9A

*Scomber thazard* Lacepède, 1800:599 (original description) Lacepède, 1801:9–13 (description, off New Guinea); no type-specimens extant.

*Auxis taso* Commerson, 1831 in Cuvier and Valenciennes, 1831:146–148 (original description based on *Scomber taso* Commerson, New Guinea).

*Auxis tapeinosoma* Bleeker, 1854:408–409 (original description, Nagasaki, Japan); holotype: RMNH 6050 (see Boeseman, 1964:465, pl. 3, fig. 10).

Table 2
Number of gill rakers in populations of *Auxis*.

*Auxis hira* Kishinouye, 1915:23–24, fig. 16 (original description, Japan); no type-specimens known. Kishinouye, 1923:462–463, pl. 31, fig. 55 (anatomy).

**Diagnosis.** *Auxis thazard thazard* has fewer gill rakers, 36–44, usually 38–42 (Table 2); a greater body depth at the anal-fin origin (Fig. 10); a longer pectoral fin (Fig. 11); and a wider corselet (Fig. 12) than has *A. thazard brachydorax*.

**Description.** Corselet narrow under second dorsal-fin origin (1–6 scales, usually 3, Table 1). Dorsal scaleless area extends anteriorly beyond P1 tip (1–16 mm, usually 3–12 mm, Fig. 5). Width of corselet under second dorsal-fin origin 0.5–3.5 mm, usually 0.5–1.0 mm (Fig. 3).

**Types.** *Scomber thazard* Lacepède, 1800. Neotype USNM 265418 (274 mm FL), Indonesia, Moluccas, Halmahera I., 0°58′N, 127°56′E; 12 Mar 1979; herein designated. Pectoral fin 41.2 mm, anterior extent of dorsal scaleless area 10.9 mm anterior to tip of pectoral fin, width of corselet under second dorsal-fin origin 1.4 mm, 3 scales in corselet under second dorsal-fin origin, gill rakers 10 + 31 = 41. Fig. 9A.

*Auxis tapeinosoma* Bleeker, 1854. Holotype RMNH 6050 (200 mm FL), Japan, Nagasaki; S.N. Wolff. Pectoral fin 20.5 mm; 2 scales in corselet under second dorsal-fin origin; gill rakers 10 + 30 = 40. Photograph of type presented by Boeseman (1964, pl. 3, fig. 10).

**Material examined.** 194 specimens (44.8–472 mm FL) from 94 collections.

**Western Atlantic.** 10 specimens (240–471 mm FL) from 10 collections.

**Auxis thazard brachydorax** Collette and Aandl, new subspecies

**Fig. 9B**

**Diagnosis** Auxis thazard brachydorax has more gill rakers, 40–48, usually 43–48 (Table 2), a shallower body depth at the anal-fin origin (Fig. 10), a shorter pectoral fin (Fig. 11), and a narrower corselet (Fig. 12) than *A. thazard* thazard.

**Description** Corselet narrow under second dorsal-fin origin (1–8 scales rows wide, usually 1–3, Table 1). Dorsal bare area extends anteriorly beyond tip of pectoral fins. Width of corselet under second dorsal 0.5–3.5 mm, usually 0.5–1.0 mm (Fig. 3).

**Etymology** We use the name that Fitch and Roedel used in their manuscript, *brachydorax* from the Greek *brachys* (short) and *dora* (hide) in reference to the narrow corselet. Carl L. Hubbs suggested this
name in a memo dated 1 Feb 1951 to W.I. Follett, concerning an edition of their California fish list, with copies to Fitch and Roedel.

**Material examined** 73 specimens (205–400 mm FL) from 29 collections.

**Holotype** USNM 320406 (352 mm FL); 7°51'N, 99°51'W; Olympia; 16 Aug 1991. Pectoral fin 48.9 mm, anterior extent of dorsal scaleless area 10.0 mm anterior to tip of pectoral fin, width of corselet under second dorsal-fin origin 0.9 mm, 3 scales in corselet under second dorsal-fin origin, gill rakers 10 + 35 = 45. See Fig. 9B.

**Paratypes from the eastern Pacific** 48 specimens (205–400 mm FL) from 21 collections.

**Aeixs rochei** (Risso, 1810)

**Bullet tuna**

**Diagnosis** *Aeixs rochei* has a wider corselet under the second dorsal-fin origin, 5 or more scales wide, usually 7–15 (Table 1), and the anterior margin of the scaleless area above the corselet does not reach the tip of the pectoral fin (Fig. 1). Color pattern: 15 or more fairly broad, nearly vertical dark bars in the scaleless area above the lateral line (Figs. 1 and 6).

**Geographical distribution** Cosmopolitan in warm waters (Fig. 7). Both species occur off southeastern Brazil (see distribution of *A. thazard*). Most confirmed records of *Aeixs* from the Mediterranean Sea are *A. rochei*, with the exception of two specimens of *A. thazard* from Haifa, Israel.

**Habitat and biology** (From literature summarized in Uchida, 1981, and Collette and Nauen 1983:30.) An epipelagic, neritic, and oceanic species. The spawning season may vary regionally depending on the hydrographical regime. In many parts of the Mediterranean and in the Straits of Gibraltar, maturing fish are common from May onwards, and more than 30% are spent by September. In large areas of the Gulf of Mexico, peaks of batch spawning are reported from March to April and from June to August, whereas in coastal waters from Cape Hatteras to Cuba and in the Straits of Florida, the spawning season begins in February. Indirect evidence suggests that the season extends at least from June through July off Taiwan and from May through August off southern Japan, as indicated by gonad indices and larval counts, respectively. Fecundity ranges between 31,000 and 103,000 eggs per spawning according to size of the fish. Food consists largely of small fishes, particularly anchovies and other clupeids (Etchevers, 1976).

**Size** Maximum fork length is 500 mm in Japanese catches, commonly to 350 mm. Common fork lengths in the Indian Ocean range between 150 and 250 mm. Fork length at first maturity off Gibraltar is 350 mm for females and 355 mm for males (Rodríguez-Roda, 1966).

**Subspecies** The eastern Pacific population of *A. rochei* has more scales in the corselet under the second dorsal fin: therefore we describe it as a separate subspecies. ANCOVA on morphometric characters for populations of *A. rochei* were not significant, possibly because of the small size range (300–365 mm) for the eastern Pacific sample, but no significant differences
were found between morphometric features for the eastern Pacific population and other populations.

**Auxis rochei rochei** (Risso, 1810)

**Fig. 13, A and B**

*Scomber Rochei* Risso, 1810:165–167 (original description, Nice); holotype MNHN A. 5808, Nice). *Scomber Bisus* Rafinesque, 1810a:45, pl. II (upper fig.) (original description, Sicily); no type material. Rafinesque, 1810b:20 (Sicily).

---

**Figure 13**

Type specimens of *Auxis rochei*. (A) Holotype of *Scomber rochei* Risso, 1810 and lectotype of *Auxis vulgaris* Cuvier, 1831; MNHN A.5808; 395 mm FL; Mediterranean Sea, Nice. (B) Holotype of *Auxis ramsayi* Castelnau, 1879; MNHN A.1241; 290 mm FL; Australia, Sydney. (C) Holotype of *Auxis rochei eudorax* n. ssp.; LACM 6712-1; 330 mm FL; California, 23 Fathom Bank.

**Auxis Ramsayi** Castelnau, 1879: 382 (original description, Port Jackson (Sydney), New South Wales, Australia); holotype MNHN A.1241.

**Auxis maru** Kishinouye, 1915:24 (original description, Japan); no type specimens known. Kishinouye, 1923:463464, pl. 31, fig. 56 (anatomy).

**Diagnosis** *Auxis rochei rochei* has fewer corselet scales, 5–24 (usually 6–19, Table 1), under the second dorsal-fin origin than *A. rochei eudorax*, 14–30 (usually 20–25).

**Description** Gill rakers 39–49, usually 41–47 in the Mediterranean, Gulf of Guinea, and Indo-West Pacific (Table 2); 39–46, usually 40–44 in the western Atlantic. The western Atlantic population has a narrower corselet (usually 6–9 scales wide under the second dorsal-fin origin compared with 8–19 in the eastern Atlantic and Indo-Pacific, Table 1) but appears best referred to as *A. r. rochei*. Corselet width under second dorsal-fin origin (Fig. 3) 2.0–10.0 mm, usually 3.0–7.0 mm, except in the western Atlantic where corselet width is only 1.0–4.0 mm, usually 1.5–3.5 mm. Dorsal scaleless area fails to reach pectoral-fin tip (Fig. 1) by up to 23.0 mm (Fig. 5); usually 3.0–17.0 mm in the Mediterranean, Gulf of Guinea, and Indo-West Pacific; may extend a little anterior to the pectoral-fin tip in the western Atlantic (Fig. 8).

**Types** *Scomber rochei* Risso, 1810. Holotype MNHN A.5808 (395 mm FL). Mediterranean, Nice. Pectoral fin 50.1 mm; anterior extent of dorsal scaleless area extends 10.3 mm posterior to tip of pectoral fin; width of corselet under second dorsal-fin origin 3.7 mm; 12 scales in corselet under second dorsal-fin origin; gill rakers 9 + 33 = 42. Fig. 13A.

**Auxis vulgaris** Cuvier, 1831. Lectotype MNHN A.5808, herein selected. This specimen is also the holotype of *A. rochei*; thus *A. vulgaris* is an objective synonym of *A. rochei*.

**Auxis thynnoides** Bleeker, 1855. Holotype RMNH 6049 (260 mm FL), Indonesia, Ternate; C.F. Goldman. Pectoral fin broken, 27.2+ mm; dorsal scaleless area extends does not reach tip of pectoral fin; 5 scales in corselet under second dorsal-fin origin; gill rakers 11 + 36 = 47. Photograph of holotype in Boeseman (1964, pl. 3, fig. 9).

**Auxis Ramsayi** Castelnau, 1879. Holotype MNHN A.1241 (290 mm FL), Australia, New South Wales, Sydney. Pectoral fin 34.7 mm; anterior extent of dorsal scaleless area 12.7 mm posterior to tip of pectoral fin; width of corselet under second dorsal-fin origin 5.7 mm; 15 scales in corselet under second dorsal-fin origin; gill rakers 10 + 33 = 43. Fig. 13B.

**Material examined** 261 specimens (58.7–443 mm FL) from 102 collections.

**Western Atlantic** 37 specimens (96.4–442 mm FL) from 21 collections.

*Auxis rochei eudorax* Collette and Aandall, new subspecies

**Fig. 13C**

**Diagnosis** *Auxis rochei eudorax* has more corselet scales under the second dorsal-fin origin (Table 1), 14–30 (usually 20–25) than *A. rochei rochei*, 5–24 (usually 6–19).

**Description** Gill rakers 43–48, usually 44–47 (Table 2). Corselet width under second dorsal-fin origin 5.0–11.0 mm, usually 7.0–10.0 mm (Fig. 3).

**Etymology** We use the name that Fitch and Roedel used in their manuscript, *eudorax* from the Greek.
eu (well) and dora (hide) in reference to the wide or well-developed corselet. Carl L. Hubbs suggested this name in a memo dated 1 Feb 1951 to W.I. Follett, concerning an edition of their California fish list, with copies to Fitch and Roedel.

**Material examined** 30 specimens (300–365 mm FL) from 17 collections.

**Holotype** LACM 6712-1 (330 mm FL); CA, 23 Fathom Bank; 13 Jan 1956; R.D. Collyer; field number SSY 1-2. Pectoral fin 41.7 mm; anterior extent of dorsal scaleless area extends 8.1 mm posterior to tip of pectoral fin; width of corselet under second dorsal-fin origin 10.2 mm; 25 scales in corselet under second dorsal-fin origin; gill rakers 11 + 36 = 47. See Fig. 13C.

**Paratypes from the eastern Pacific** 29 specimens (300–365 mm FL) from 17 collections.

**Acknowledgments**

We thank the curators and staffs of the many collections housing specimens of *Auxis* for permission to study and borrow material: AMNH (Gareth Nelson); AMS (John R. Paxton); ANSP (Eugenia Böhleke); BMNH (Nigel Merrett); BPBM (John E. Randall); CAS (William N. Eschmeyer, Pearl Sonoda); FMNH (Barry Chernoff); GMBL (William D. Anderson, Jr.); HUJ (Dani Golani); ISH (now ZMH, Matthias Stehman); LACM (Robert J. Lavenberg, Jeffrey A. Seigel); MCZ (Karsten Hartel); MNHN (Jean-Claude Hureau, Marie-Louise Bauchot); MNMZ (Clive Roberts); NMW (Barbara Herzig); ROM (Richard Winterbottom); SIO (Richard Rosenblatt); TU (Royal D. Suttikus); UF (George Burgess); UMMZ (Reeve M. Bailey, William L. Fink); ZRC (formerly USDZ, Kelvin Lim); and ZUMT (Yoshiaki Tominaga). Masahiro Aizawa (ZUMT) was of particular help in translating localities of Japanese *Auxis* while the first author was working in the ZUMT collections. William J. Richards generously donated specimens of *Auxis* from the Gulf of Guinea and provided data and draft manuscripts of work he had in progress on *Auxis*. Robert J. Lavenberg (LACM) kindly gave the first author free access to John Fitch’s data and correspondence concerning *Auxis*. Walter Fischer, then with FAO Rome, made it possible for the first author to participate in the FAO workshop in Cochin, India, in 1980 and to collect and examine fresh material; Kent Carpenter did likewise for the FAO workshop in Manila, Philippines, in 1995. Inocencio Ronquillo sent specimens of *Auxis* from the Philippines. Thomas Munroe, Martha Nizinski, and Stanley Weitzman assisted with computer analysis of morphometric data. Deborah Loffler and Ruth Gibbons plotted localities for the distribution map. John E. Randall generously provided the slides for the color plate (Fig. 6). Ruth Gibbons painstakingly took and retook photos of the type specimens (Figs. 9 and 13). Thomas Munroe and William Richards made valuable comments on drafts of the manuscript.
