Preliminary Field Report

Herpetology

Jan. - March 1985

Three herpetologists (Roy W. McDiarmid, Rex B. Cocroft, Alfredo Paolillo) worked at Neblina from 25 January to 4 March 1985. Amphibians and reptiles were collected at the Base Camp, Whitewater River, and Loma de las Pinas in the lowlands and at Camps I, II, VII, X and XI on the Cerro. A total of 610 specimens were collected, totaling 127 specimens of reptiles (2 turtles, 1 crocodile, 31 snakes, 92 lizards) of 45 species and 483 specimens of amphibians (all frogs) of 34 species. In general, the collection covered many areas, sampled several species new for the project and added at least 5 new species to the already large list. We estimate that as many as 15 new species of amphibians and reptiles were collected during the total project; this represents about 20% of the total fauna and more than 90% of the highland fauna. This high number of new species (including at least 2 new genera) is truly remarkable.

In addition to adding several species to the Neblina list and capturing many species for the first time in Venezuela, we were able to get considerable information regarding the life history and reproduction of many species of frogs. Tape recordings of 22 species were made, 12 of which are new species or genera; tadpoles of 10 species were collected.

Several of the species collected at high elevations show modified reproductive modes (e.g., direct development in most species of frogs) and one has a highly modified tadpole with a large sucker for living in fast currents. In addition, three species (the new bufonid genus and the two species of the lizard Riolama) add considerably to our understanding of the zoogeographic patterns characteristic of Pantepui and tie the eastern

(Roraima, etc.) tepuis with the western ones (Neblina). The first species with Andean affinities was recorded with the capture of *Phenacosaurus*, a lizard known previously only from the Andes and Coastal Range.

Finally, Bill Buck, Tom Givnish and I studied the survival of *Neblinaria* in an extensively burned area near Camp X. Our results clearly indicate that the endemic genus is fire adapted and suggest that fires may be of relatively common occurrence on Neblina.
