Aporphine Alkaloids from *Guatteria* spp. with Leishmanicidal Activity

Hector Montenegro¹, Marcelino Gutiérrez¹,², Luz I. Romero³, Eduardo Ortega-Barria⁴, Todd L. Capson⁵, Luis Cubilla Ríos¹

Abstract

Fractionation of *Guatteria amplifolia* yielded the alkaloids xylopine (1), norcuciferine (4), lyciscamine (6), and laudanosine (5). Fractionation of *Guatteria dumbetorum* yielded the alkaloids cryptodine (2) and norcuciferine (3). Compounds 1–4 demonstrated significant activity against *Leishmania mexicana* and *L. panamensis*. Xylopine (1) was among the most active compounds (LD₅₀ = 3 μM) and showed a 37-fold higher toxicity towards *L. mexicana* than macrophages, the regular host cells of *Leishmania* spp.

The genus *Guatteria*, from the neotropical Annonaceae, has 279 species including *Guatteria amplifolia* Triana & Planch and *Guatteria dumbetorum* R.E. Fr. [1]. Previous studies of *G. amplifolia* yielded aporphine alkaloids [2], [3], and extracts showed activity against *Leishmania* spp. [4]. We carried out fractionation of leaf extracts from *G. amplifolia* and *G. dumbetorum* in order to find compounds to treat leishmaniasis, a parasitic disease for which plant natural products represent a potential source of new medicines [5], [6].

Following activity against the promastigote form of *Leishmania mexicana*, the aporphine alkaloids xylopine (1) and norcuciferine (4), the o xoaporphine alkaloid, lyciscamine (6) and the tetrahydrobenzylisoquinoline alkaloid, laudanosine (5) were isolated from *Guatteria amplifolia* (Fig. 1). From *Guatteria dumbetorum*, aporphine alkaloids cryptodine (2) and norcuciferine (3) were isolated. This is the first report of alkaloids 1, 5 and 6 from *G. amplifolia* and the first report of 5 from the Annonaceae family. Compounds 1 and 2 showed the greatest leishmanicidal activity (IC₅₀ = 3 μM against *L. mexicana*) followed by 3 and 4 (24 and 14 μM, respectively). Comparable results were obtained with *L. panamensis* (Table 1). Neither 5 nor 6 showed significant leish-

Fig. 1 Structures of xylpine (1), cryptodorine (2), normantenine (3), normuciferine (4), laudanosine (5) and lycasicamine (6). The absolute configurations at position 6α for compounds 1 – 4 are as follows: (1) R, (2) S, (3) S, (4) S.

manicidal activity (data not shown). Compounds 1 – 4 were evaluated in macrophages and in human foreskin fibroblasts [15]. The Selectivity Index in Table 1 indicates a 37-fold higher toxicity of 1 towards L. mexicana than macrophages, the regular host cells of Leishmania.

Materials and Methods

IR spectra were measured on a Perkin-Elmer 1699 spectrophotometer. NMR spectra were recorded on 300 and 500 MHz Bruker NMR spectrometers. Low resolution EIMS (70 eV) were collected on a Jeol SX 102A mass spectrometer. Optical rotations were determined on a Perkin-Elmer 241 polarimeter.

Leaves of Guatteria amplitofila and G. dumetorum were collected in the Barro Colorado Natural Monument in the Republic of Panama. The taxonomy was confirmed by Professor Mireya Correa of the Smithsonian Tropical Research Institute. Vouchers were deposited at the University of Panama (G. amplitofila and G. dumetorum voucher numbers PMA 50979 and PMA 50980, respectively). Fresh young leaves were homogenized in 30 g aliquots with 240 mL of MeOH for 30 s in a Waring blender followed by treatment with a Polytron homogenizer (Brinkmann Instruments). After filtration, the marc was washed with 150 mL of EtOAc. The crude extract (30 g) from G. amplitofila was partitioned between hexane and MeOH. The residue from the MeOH fraction (18.5 g) was partitioned between EtOAc and water. The EtOAc fraction was subjected to acid-base extraction yielding Fraction A (2.3 g). Fr. A was chromatographed on a column of basic alumina (4 × 40 cm) (Merck type T, 70 – 230 mesh) and eluted with CHCl₃ (700 mL), CHCl₃/MeOH (75:25, 400 mL), CHCl₃/ MeOH (67:73, 750 mL), and 100% MeOH (400 mL), and the fractions were combined according to their TLC profile into Frs. 1 – 5. Fr. 1 yielded 5 (370 mg), tr of 5: between 240 – 810 mL, RF: 0.65, detection of eluates by TLC (see below). Fr. 2 (1.03 g), between 810 – 1370 mL, was chromatographed by preparative reverse-phase TLC (RP-18, Merck) with CHCl₃/acetonitrile/NH₄OH (4:1:0.1), yielding 4 (40 mg), RF 4: 0.57, and Fr 2a (730 mg), RF Fr 2a: 0.5. Fr. 2a was subjected to preparative TLC (Whatman, PCKF, 500 μm) with CHCl₃/hexane/NH₄OH (2:1:1), yielding Fr. 2b (57 mg), RF Fr 2b: 0.42, which was purified by reverse-phase HPLC (YMC ODS-A S-5 μm, 4.6 × 250 mm) with MeOH/water/Et₂N (70:30:0.1), 1.0 mL/min, yielding 1 (37 mg, tr of 1: 20 min). Lycasicamine (6) was obtained from 153 g of Fr. A by column chromatography on silica gel 60 (37 – 75 microns, 1.5 × 15 cm), 100% acetone (1300 mL), acetone/MeOH (91:9:600 mL) yielding 90 mg of 6, tr of 6: between 950 and 1550 mL, RF 6: 0.22.

The crude extract (20 g) from G. dumetorum was subjected to solvent partition and acid-base extraction as described for G. amplitofila yielding fraction B (645 mg). Fr. B was chromatographed on a column of silica gel 60 (37 – 75 μm, 2.5 × 28 cm) and eluted with 800 mL of CHCl₃/hexane/NH₄OH (2:1:1), yielding a mixture of 2 and 3 (96 mg, tr of the mixture of 2 and 3: between 190 mL – 230 mL), which was then subjected to preparative TLC (Whatman, PCKF, 500 μm) and developed with CHCl₃/ hexane/NH₄OH (2:1:1), yielding 2 (50 mg) and 3 (15 mg), RF 2: 0.25, RF 3: 0.20, monitoring of eluates by TLC (silica gel) CHCl₃/hexane/NH₄OH 2:1:1, detection Dragendorff reagent.

Structures for 1 – 6 were determined by optical rotation, MS, UV, IR, 1D and 2D 1H-NMR and 13C-NMR experiments and by comparisons with the literature data: [7][8],[9]; 2, 3 [8],[9]; 4, 6 [7],[9]; 5 [10], [11]. Compounds 1: [α]D²: -28.18° (MeOH, c 0.001); 2: [α]D²: +19.67° (CHCl₃, c 0.001); 3: [α]D²: +85° (EtOH, c 0.75); 4: [α]D²: +138° (EtOH, c 0.22); 5: [α]D²: +43° (CHCl₃, c 0.03). Copies of original spectra are obtainable from the author of correspondence.

*Results are expressed as IC₅₀ (Inhibitory Concentration), the concentration of compound that inhibited 50% growth of the parasite or cell line. Mean values of the IC₅₀ (μM ± standard deviation) were determined by testing each concentration of sample in triplicate.*

*HFF (Human foreskin fibroblasts).*

*Sf (Selectivity Index) is a measure of the IC₅₀ values obtained in macrophages and HFF, respectively, divided by the IC₅₀ in L. mexicana.*

Letter... Planta Med 2003; 69: 677–679
L. mexicana MOHM/B2/82/BELZ and L. panamensis MOHM/PA/71/LS 91 were cultured using established protocols [12]. The study used a colorimetric Leishmania spp. promastigote growth assay which is based upon the reduction of sodium 2,3-bis-[2-methoxy-4-nitro-5-sulphophenyl]-2H-tetrazolium-5-carboxanilide (XTT) [13], and amphotericin-B was used as a positive control [14]. Cell toxicity was assessed by the reduction of XTT by either human foreskin fibroblasts or murine macrophages (cell line J774) [15].
