

RONALD J. McGINLEY

#### SERIES PUBLICATIONS OF THE SMITHSONIAN INSTITUTION

Emphasis upon publication as a means of "diffusing knowledge" was expressed by the first Secretary of the Smithsonian. In his formal plan for the Institution, Joseph Henry outlined a program that included the following statement: "It is proposed to publish a series of reports, giving an account of the new discoveries in science, and of the changes made from year to year in all branches of knowledge." This theme of basic research has been adhered to through the years by thousands of titles issued in series publications under the Smithsonian imprint, commencing with *Smithsonian Contributions to Knowledge* in 1848 and continuing with the following active series:

Smithsonian Contributions to Anthropology
Smithsonian Contributions to Astrophysics
Smithsonian Contributions to Botany
Smithsonian Contributions to the Earth Sciences
Smithsonian Contributions to the Marine Sciences
Smithsonian Contributions to Paleobiology
Smithsonian Contributions to Zoology
Smithsonian Folklife Studies
Smithsonian Studies in Air and Space
Smithsonian Studies in History and Technology

In these series, the Institution publishes small papers and full-scale monographs that report the research and collections of its various museums and bureaux or of professional colleagues in the world of science and scholarship. The publications are distributed by mailing lists to libraries, universities, and similar institutions throughout the world.

Papers or monographs' submitted for series publication are received by the Smithsonian Institution Press, subject to its own review for format and style, only through departments of the various Smithsonian museums or bureaux, where the manuscripts are given substantive review. Press requirements for manuscript and art preparation are outlined on the inside back cover.

#### ABSTRACT

McGinley, Ronald J. Studies of Halictinae (Apoidea: Halictidae), I: Revision of New World Lasioglossum Curtis. Smithsonian Contributions to Zoology, number 429, 294 pages, 746 figures, 4 tables, 1986.—The New World species of Lasioglossum (sensu stricto) are revised, based on a study of approximately 25,000 specimens. Fifty-one species are recognized, with 20 described as new. All species are fully described and diagnosed. Flight records are summarized with histogram plots, distributions indicated by dot maps, and illustrated keys provided for species identification. Floral association data are summarized (5348 records) and compared to similar data for California Bombini. The association of Lasioglossum species with phoretic histiostomatid and scuticarid mites is reviewed and infestation levels for involved species presented. A preliminary study of the phylogenetic interrelationships of included species is presented, which includes a character matrix intended to facilitate future cladistic efforts.

The new species are L. acarophilum, L. acuminatum, L. anhypops, L. argutum, L. asaphes, L. bajaense, L. cercothrix, L. channelense, L. eickworti, L. katyae, L. lampronotum, L. orphnaeum, L. paraforbesii, L. parkeri, L. perscabrum, L. rupticristum, L. sandrae, L. timberlakei, L. tropidonotum, and L. xyriotropis. Lasioglossum egregium (Vachal) is elevated from junior synonymy, and the following names relegated to synonymy: Halictus supercretus Cockerell under L. circinatum (Vachal); H. ripariellus Cockerell under L. colatum (Vachal); H. matensis Friese under L. costale (Vachal); H. sericeus Friese under L. crocoturum (Vachal); H. cyaneiceps Cockerell under L. desertum (Smith); H. olympiae subangustus Cockerell under L. sisymbrii (Cockerell). A neotype is designated for H. trizonatus Cresson and lectotypes designated for H. costalis Vachal, H. matensis Friese, H. crocoturus Vachal, H. desertus Smith, H. fuscipennis Smith, H. manitouellus Cockerell, H. pacificus Cockerell, and H. sisymbrii Cockerell. Halictus schenckii is treated as a nomen dubium.

OFFICIAL PUBLICATION DATE is handstamped in a limited number of initial copies and is recorded in the Institution's annual report, Smithsonian Year. SERIES COVER DESIGN: The coral Montastrea cavernosa (Linnaeus).

### Introduction

Halictine bees have attracted increased attention during the past 25 years because of growing interest in social biology and its evolution. The included species display a wide variety of nesting biologies, ranging from those where individuals are strictly solitary to those that form complex, primitively eusocial colonies (Michener, 1974). Furthermore, the nests of many species can be maintained and manipulated under laboratory conditions. However, while biological information for the group has dramatically increased, our understanding of halictine taxonomy has lagged behind, with the notable exceptions of Eickwort's (1969a) generic study of the Augochlorini, Michener's (1978) classification of nonparasitic genera with strong venation, Ordway's (1966) review of Augochlorella, Robert's (1972) review of Agapostemon, and Ebmer's extensive work on Old World halictids. In a series of papers, Ebmer has reviewed the halictine faunas of central Europe (1970, 1972a,b, 1974c, 1975, 1976b), Iberia (1979), Morocco (1976a), Crete (1981), Israel (1974b), Afghanistan (1974a), Iran

(1978a), and Asia (1980, 1983), including Korea (1978b), Manchuria (1978c), and Mongolia (1982). To date, the dominant halictine genera of the Nearctic Region, *Dialictus, Evylaeus, Lasioglossum* (sensu stricto), and the cleptoparasitic *Sphecodes*, have never been comprehensively reviewed. Eickwort is currently revising the Nearctic species of *Dialictus* (188 specific names listed for north of the Mexican border, Hurd, 1979).

The purpose of the present paper is to review and stabilize the taxonomy of the New World Lasinglessum. It is hoped that this work will provide outgroup information that will facilitate future taxonomic and phylogenetic studies of Evylaeus and Dialictus, both of which include numerous social species. Although phylogenetic analyses of morphological characters will be important in the study of halictine comparative behavior, phylogenetic considerations are herein only preliminary in scope; this is for two reasons: the outgroup structure of genera related to Lasioglossum is poorly understood, with a number of these genera being undoubtedly artificial as discussed below; second, I have not yet studied the many Old World species of this Holarctic group.

In the New World, Lasioglossum ranges from

Ronald J. McGinley, Department of Entomology, National Museum of Natural History, Smithsonian Institution, Washington, D.C. 20560. the Northwest Territories in Canada (L. athabascence) to Panama (L. crocoturum, L. uyacicola). Prior to the present work, 36 specific names were recognized for Lasioglossum in this area. Of these, five are now relegated to junior synonymy, one (Halictus schenckii) is treated as a nomen dubium, and one (L. egregium) is elevated from junior synonymy. With 20 new species recognized herein (15 from Mexico and Central America) the number of valid New World Lasioglossum species now stands at 51. Ebmer's papers (cited above) indicate that at least 80 specific and eight subspecific Lasioglossum names are currently recognized from the Old World fauna.

HISTORICAL ACCOUNT.—Curtis (1833), recognizing the heterogeneity of the genus Halictus Latreille, 1804, described the genus Lasioglossum to contain a new species having basal hair bands on the abdominal terga that contrasted with the apical hair bands of other Halictus species known to him. In his description of L. tricingulum, Curtis mentions that the labium is "rather long lanceolate and very pubescent on the sides and at the back ...," hence the name Lasioglossum or "hairy-tongue." This is somewhat misleading in that the glossae of Lasioglossum species are no more hairy than those of other halictids. Subsequent workers ignored Curtis' generic differentiation and continued to describe new species under the older, inclusive concept of Halictus. It was not until 1902 that Robertson wrote, "the so-called genus Halictus of authors seems to be altogether too heterogenous. I restore Lasioglossum and propose two other new genera [Evylaeus and Chloralictus]." His generic concepts were based primarily on characters of the forewing, in particular the strength or weakness of certain cross-veins (1 r-m, 2 r-m). Later in 1918 Robertson further subdivided his already restricted concept of Lasioglossum by proposing the genus Curtisapis to include such forms as L. coriaceum and L. fuscipenne, which are somewhat opaque compared to the relatively shiny L. leucozonium and L. zonulum. Although this was followed by some workers, including Cockerell, most bee taxonomists avoided this tendency to oversplit generic concepts. Michener (1944) recognzied both Lasioglossum and Halictus at the generic level but relegated Evylaeus, Chloralictus, Dialictus, and related taxa to subgeneric status under Lasioglossum. Similar broad generic concepts are used by virtually all Old World bee taxonomists. In recent years, beginning with Mitchell (1960) and later formalized by Hurd (1979), there has been a tendency among many workers in the United States to utilize the more restricted generic concepts of Robertson. Though I follow this approach in dealing with Lasioglossum (sensu stricto), it must be emphasized that the generic limits are poorly understood at present and will undoubtedly be revised in the future, as was pointed out by Michener (1974:287). Because most halictine groups have never been comprehensively reviewed, the focus of most current halictine systematic work is alpha-taxonomic; I plan to follow this phase with analyses of higher categories.

BIOLOGY.—Very little information on the biology of New World Lasioglossum has been published. Most biological accounts deal with floral associations (e.g., Graenicher (1909), Moldenke and Neff (1974), and Robertson (1929)). Information on nesting biology of most New World species is limited mostly to brief notes, as for L. forbesii (Atwood, 1933), L. leucozonium (Knerer, 1969; Knerer and MacKay, 1969), and L. zonulum (Atwood, 1933; Knerer and Atwood, 1962). Some information is also now available on Dufour's gland chemistry for L. coriaceum, L. fuscipenne, and L. leucozonium (Duffield et al., 1981; Hefetz et al., 1978).

With his discussion of *L. leucozonium* from Nova Scotia, Atwood (1933) provided the most detailed account available on nesting biology for a New World *Lasioglossum*. He provided a general description of nest sites, nest structure, and burrow dimensions. All immature stages were excavated but not described (to date, the immature stages of *Lasioglossum* have not been described). Even though most *Lasioglossum* species are assumed to be solitary, Atwood made the interesting observation that "in some cases two

females must co-operate in digging, because more than one adult was occasionally seen in a hole much earlier than the appearance of the pupae in the cells." Communal behavior has also been reported by Knerer and Schwarz (1976) for L. bimaculatum (Dours) in the Mediterranean region. In the same paper, L. aegyptiellum (Strand) was also reported to be primitively eusocial in the same region. Obviously much more biological work is needed before the distribution of sociality in the genus can be seriously addressed.

The biological associations of Lasioglossum with other invertebrates account for much of the biological literature on the genus. Like other apoid groups, Lasioglossum species are commonly taken as prey items by Philanthus wasps. This association has been reported for L. coriaceum, fuscipenne, leucozonium, manitouellum, and sisymbrii (Alcock and Gamboa, 1975; Evans, 1955, 1975, 1982; Evans and Lin, 1959; Reinhard, 1924). The *Philanthus* species involved are listed in the Lasioglossum synonymies. The association between Lasioglossum and phoretic mites has been reported for L. coriaceum (Eickwort, 1979) and L. titusi (Linsley and MacSwain, 1959; Whitsel and Schoeppner, 1971; Eickwort, 1979; Delfinado and Baker, 1976). This is reviewed for all Lasinglossum species in a following section of this paper. The only report of Lasioglossum parasitization is that of a conopid parasitoid (Thecophora occidensis) associated with L. forbesii in southern Ontario (Knerer and Atwood, 1967).

Linsley (1962) described the "sleeping" behavior of *L. sisymbrii* from southern Arizona. Females "sleep" individually on flower heads and are tolerant of other hymenopteran species "sleeping" nearby.

ACKNOWLEDGMENTS.—This study would not have been possible were it not for the cooperation of the many curators and institutions who kindly lent specimens to me. I am especially grateful to those curators who arranged the loan of primary type material (these collections are indicated with an asterisk in the following listing). The acronyms used follow those of Griffiths (1980) with minor modifications.

An attempt was made to augment the level of illustrative materials included in this monographic effort. This would not have been possible without the unique support provided by the Smithsonian Institution and by the following people whose help I greatly appreciate. S.G. Braden, W.R. Brown, and H. Wolf took the scanning electron micrographs; W.D. Hope provided critical materials and advice on methods for mounting very small specimens on SEM stubs; K. Ruetzler provided the use of his compound microscope to photograph the sternal plates; K.P. Smith photographed the sterna and also provided translations of Vachal's papers; V.E. Krantz photographed heads and wings and provided prints of all photographs utilized; H.H. Aceto assisted in map production by photoreducing oversize base maps and acetate overlays. I would also like to thank D.C. Fisher and B.J. Spann for encouraging the use of the illustrated keys and for their assistance in all matters

related to the final production of this paper. Special thanks for artistic support go to E.R.S. Hodges, who provided all of the excellent drawings included as well as general advice and support throughout the course of this study.

This project would have taken far longer to complete were it not for the able assistance of S. Shanks, who provided general technical help and discussion. I also thank N.E. Woodley for general discussions and comments and G.C. Steyskal for help in forming Greek and Latin names and M.F. Mickevich for invaluable help in the phylogenetic analysis and running of the PHYSYS program. Finally, I would like to express my thanks to R.W. Thorp and G.C. Eickwort, who critically reviewed and greatly improved the manuscript. Eickwort encouraged this study from its inception and generously provided critical specimens and information throughout.

#### MATERIALS AND METHODS

This study was based on an examination of approximately 25,000 specimens borrowed from 65 institutions and three personal collections. Institutions, curators, curatorial associates, and acronyms are listed in the Acknowledgments section. An estimate of the relative abundance of the species examined can be obtained from the checklist of New World *Lasioglossum* (Table 1).

Label data for all specimens were completely recorded. This information is presented for type material of all new species and for uncommon species with fewer than 150 known specimens. Label data for primary type material and paratypes are presented exactly as given, with bracketed annotations included to complete abbreviations or clarify ambiguous information (collection dates were not converted to the day-monthyear convention used elsewhere in this study, in order to facilitate exact label identification). For more common species, collector names and collection dates are deleted and only the county is listed where five or more localities are known within a given county. Flower records are presented in a separate section for each species, following the format of Thorp et al. (1983). The

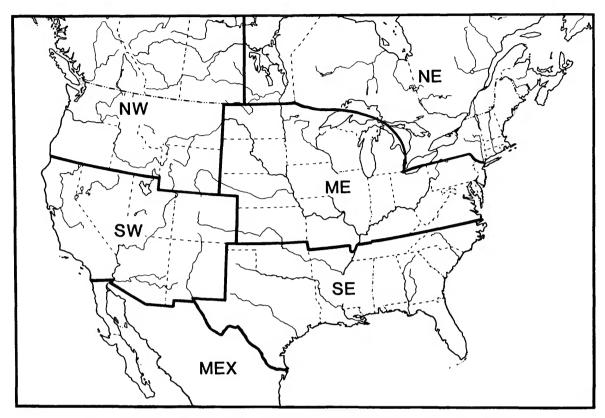

FIGURE 2.—Faunal regions and abbreviations used in histogram plots of flight data (ME = middle-eastern region, MEX = Mexico and Central America, NE = northeastern region, NW = northwestern region, SE = southeastern region, SW = southwestern region; modified from Tangelder, 1983; see "Materials and Methods").

work sheets containing complete label data, including the occurrence of phoretic mites and presence of pollen loads, are available from the author or from the Smithsonian Archives. All specimens examined were individually labeled with determination labels.

Flight-period data are summarized in histogram plots following the method of Tangelder (1983), with slight modification. The plots present the number of specimens collected for halfmonth periods. Such diagrams often plot the number of collections or lots (not specimens) for a given time unit, which removes the variable of differences in collecting intensity; however, this approach will not be sensitive to differences in species abundance through time. Given that both

approaches have drawbacks, I have chosen to plot the number of specimens collected per unit time. Following Tangelder, I have subdivided the histograms into regional subplots as presented in Figure 2. Where the number of specimens collected for a given half-month period is very small, the corresponding histogram bar is sometimes plotted at a higher specimen number in order to avoid confusion. For example, if only two specimens were collected in a half-month period, for a given scale it may only be possible to differentiate between zero, five, and 10 specimens, in which case the lowest unit of five specimens (not two) is plotted.

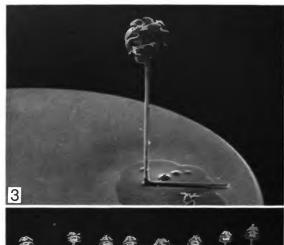

Three different base maps were used to plot species distributional data. For species occurring

in the United States and ranging into Mexico and/or Central America, a Goode map of North America was used (dot diameter equals approximately 75 miles). Mexican species were plotted using a map prepared by Y.T. Sohn (NMNH staff artist; dot diameter equals approximately 27 miles). For species occurring in the United States and/or Canada a map prepared by E.R.S. Hodges (NMNH staff artist) was used. This is a composite map consisting of a United States map prepared by the Bureau of the Census, U.S. Department of Commerce, with the Canadian provinces drawn in. Dots (diameter equals 50 miles) were applied to acetate overlays and the maps then photographically reduced by a Horizontal D.S. Process Camera (Smithsonian American History Photo Lab).

All drawings were made with a Wild M5 stereomicroscope and camera lucida. Illustrations were enlarged with a microprojector and then made bilaterally symmetrical.

Photographs of male sterna VII-VIII were taken with a Reichert Zetopan microscope and a Kam ES semiautomatic camera. The material was cleared in cold potassium hydroxide for approximately two hours and stained with acid fuschin for one hour. Remaining tissue was removed with fine dissecting needles and the sterna then mounted in glycerin under a cover slide.

Scanning electron micrographs were taken with a Cambridge 250. Specimens were coated with gold palladium and most micrographs taken at 10 keV. Specimens were cleaned with a fine brush or by applying a fine coat of rubber cement that was carefully removed after drying. Hairs were removed with small pieces of Scotch® tape held by fine forceps under a stereomicroscope. Male genitalia prepared for the SEM were not cleared with cold potassium hydroxide as were most specimens, but rather cleaned with a fine brush (some tissue in the gonobase was removed with fine forceps and needles), processed in a Samdri-790 critical-point dryer, and glued with a polyvinyl acetate (PVA) mixture to the end of a fine tungsten filament as in Figure 3. The same mounting technique was used for the labra (Figure 4) and tibial spurs.

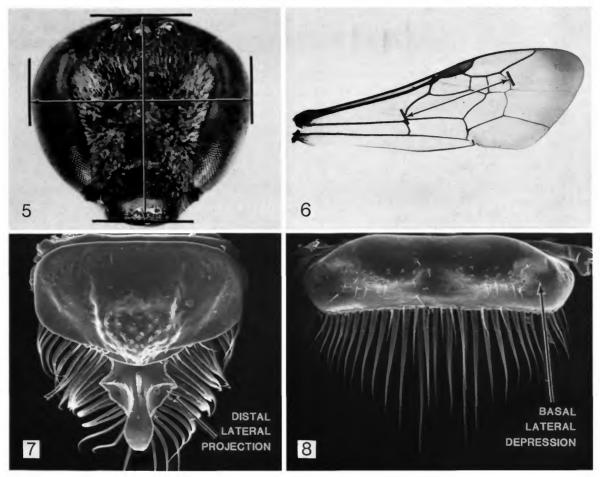

FIGURES 3, 4.—Mounting technique for SEM stubs: 3, Lasioglossum male genitalia; 4, Lasioglossum female labra.

Appendix 2 contains identifications of figures used in the keys.

The species description format generally follows that of Eickwort (1978), with the inclusion of individual character numbers intended to facilitate character comparisons between species. The descriptions are composite but were initially based on single specimens of a Lasioglossum synoptic collection that will be maintained in the NMNH collection for use by future workers. After the initial single-specimen description was completed, intraspecific character variation was included after an examination of a series of specimens (usually 20 to 30 specimens were carefully checked against the description). All measurements were taken using a Leitz stereomicroscope with an ocular micrometer at 12.5 magnification.

# DISCUSSION OF CHARACTERS

The intention of this section is to introduce the new characters used in this study and hope-

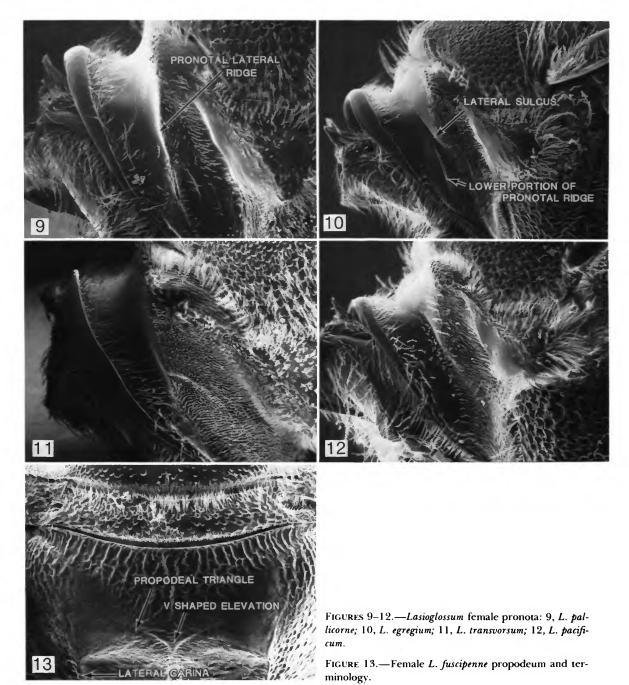

FIGURES 5-8.—Measurements and terminology: 5, Lasioglossum fuscipenne male head showing head length and width measurements; 6, L. manitouellum wing showing wing length measurement; 7, L. asaphes female labrum; 8, L. acarophilum male labrum.

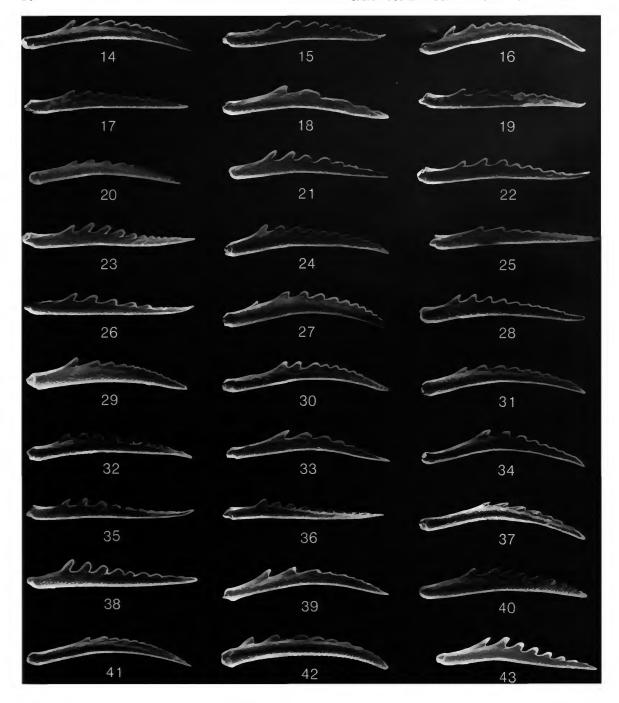

fully to remove as many general terminological ambiguities as possible. Only those characters and terms requiring clarification are discussed below (identifying character numbers are used consistently throughout).

- 1. Body length: This measurement was preferably taken from uncurled specimens; separate measurements of the head, thorax, and abdomen were tallied for highly curled bees
- 2. Wing length: Total wing length can be precisely measured only for those specimens with unworn wing tips. Because of this, wing length measurements were taken from the base of the arcuate basal vein (vein M) to the distal-most

extension of the third submarginal cell (vein 2 r-m; Figure 6).

- 3. Abdominal width: This measurement was taken at the widest point of the abdomen near the apex of tergum II.
- 4. Head length/width ratio: Head length was measured from the top of the vertex to the ventral margin of the clypeus; head width was measured at the widest point of the head across the compound eyes (Figure 5).
- 9. Clypeal projection below compound eyes: The portion of the clypeus projecting below the ventral margin of the compound eyes was reported by Eickwort (1978) for Mexalictus and varies considerably among Lasioglossum species. Because of time considerations, only a rough estimate of this projection is given, in that only one specimen for each species was measured.

11. Clypeal sulcation: The clypeus of many Lasioglossum species has a median longitudinal sulcation or groove. Although considerable intraspecific variation exists, the sulcation is clearly better defined in certain species and is especially developed in many Mexican forms. It is reported herein for possible phylogenetic consideration in the future.

24-29. Labrum: Labral terminology follows that of Eickwort (1969a:340). The females of most Lasioglossum species have what are herein termed "distal lateral projectons" that vary considerably in size and shape (Figure 7). Certain Lasioglossum males have a conspicuous depression on each side of the labrum, herein referred to as a "basal lateral depression" (Figure 8).

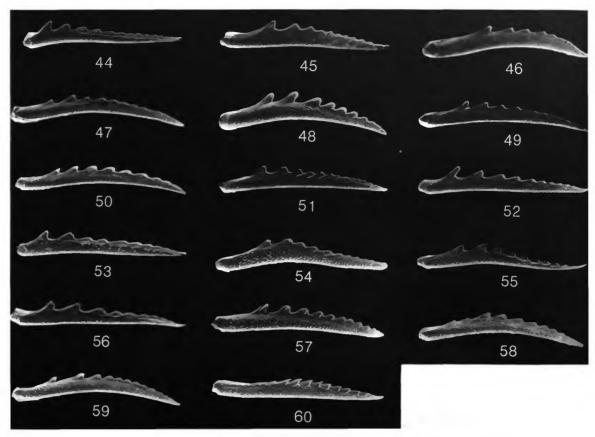

- 33, 34. Pronotal lateral ridge: The morphology of the lateral pronotum, especially the complete or incomplete nature of the pronotal lateral ridge, has been used extensively in the systematic studies of Andrena by W.E. LaBerge (1964). Based on his suggestion to examine this feature in Lasioglossum, I found this to be a most useful character for species recognition. In a number of species the ridge is complete as in L. pallicorne (Figure 9) and L. xyriotropis (Figure 732), where the ridge is very sharply edged. Occasionally the ridge will superficially appear to be complete but is actually microscopically interrupted as in L. transvorsum (Figure 11). The majority of Lasioglossum species have the ridge distinctly interrupted by an oblique lateral sulcus as in L. egregium (Figure 10). Usually the sulcus is very narrow but can be conspicuously broad as in L. pacificum (Figure 12). Where present, the lateral sulcus delimits a "lower portion of the lateral ridge" that can be sharply edged (Figure 10) to broadly rounded and inconspicuous (Figure 12).
- 40. Relative length of propodeal dorsal surface to scutellum and metanotum: As stated above for the clypeal projection (character 9), only an approximate estimate of relative propodeal length is given, because only one specimen for each species was measured.
- 43. Propodeal triangle: Terminology associated with the dorsal propodeal surface is presented in Figure 13, i.e., propodeal triangle, median V-shaped elevation and lateral carina.
  - 45. Tibial spur: Bees typically have two spurs at the

FIGURES 14-43.—Lasioglossum female inner tibial spurs: 14, L. acarophilum; 15, L. acuminatum; 16, L. aequatum; 17, L. anhypops; 18, L. argutum; 19, L. asaphes; 20, L. athabascense; 21, L. bajaense; 22, L. bardum; 23, L. cercothrix; 24, L. channelense; 25, L. circinatum; 26, L. colatum; 27, L. coriaceum; 28, L. costale; 29, L. crocoturum; 30, L. desertum; 31, L. egregium; 32, L. eickworti; 33, L. fuscipenne; 34, L. heterorhinum; 35, L. jubatum; 36, L. katyae; 37, L. lampronotum; 38, L. leucozonium; 39, L. manitouellum; 40, L. mellipes; 41, L. morrilli; 42, L. olympiae; 43, L. orphnaeum.

apex of each hind tibia, the inner one of which is variously branched or toothed in female halictines. Because this spur is usually illustrated for the group, an SEM micrograph or a drawing is provided for a representative of each species (Figures 14–60; micrographs were combined into unified plates to facilitate comparison of the subtle differences involved). However, a detailed analysis of intraspecific variation as presented by Eickwort and Fischer (1963) was not attempted. It is hoped that gross patterns of variation in spur morphology as documented in the included illustrations will be of interest to future workers considering halictine higher classification.

- 46. Lateral edge of second abdominal tergum: The shape of the second tergal edge has apparently not been previously utilized in halictine systematics. In most Lasioglossum species this edge is gently sinuate as in L. mellipes (Figure 61); however, the edge can be rounded as in L. titusi (Figure 62), nearly straight as in L. egregium (Figure 63), or sharply excavated as in L. coriaceum (Figure 64) (throughout this paper, "tergum/sternum I" refers to those sclerites of the first abdominal segment).
- 80. Acarinarium: The acarinarium (mite-containing area) in most Lasioglossum species associated with phoretic mites is a glabrous area surrounded by a conspicuous hair fringe at the base of the first abdominal tergum (Figure 72). The size and shape of the glabrous area and configuration of fringe hairs varies considerably among involved species. See "Mite Associations" section for further details.
- 82, 83. Male sternal vestiture: For most species only the vestiture of sterna IV-V is described. Hair patterns are most commonly described in terms of involving erect hair tufts (Figure 212) or adpressed lateral hair lobes/fringes along the posterior sternal edge (Figure 214). Many Lasioglossum males have what is herein termed a "median rosette of erect hairs" as in Figure 213.
- 84, 85. Male sterna VII-VIII: Sternum VII of all New World Lasioglossum (and many other halictines) has a protruding medial area herein referred to as the "median process" (Figure 66). The median process of sternum VIII is absent in many Lasioglossum species (Figure 567) but, where present, varies considerably in size and form.
- 88. Retrorse membranous lobe: The conspicuous membranous lobes found on the ventral surface of most Lasioglossum male genitalia (Figure 65) have been refered to as "retrorse lobes" by both Mitchell (1960) and Michener (1978). These structures were also called "ventral flaps" by Eickwort (1969b), who used them to characterize the Halictini (Eickwort, pers. comm., now prefers the terminology of Mitchell and Michener).

Terminology related to surface sculpturing follows Harris (1979); below, his definitions are presented (in part) and appropriate figures in the present paper cited.

FIGURES 44-60.—Lasioglossum female inner tibial spurs: 44, L. pacificum; 45, L. pallicorne; 46, L. paraforbesii; 47, L. pavonotum; 48, L. perscabrum; 49, L. pharum; 50, L. rupticristum; 51, L. sandrae; 52, L. sisymbrii; 53, L. timberlakei; 54, L. titusi; 55, L. transvorsum; 56, L. tricnicos; 57, L. trizonatum; 58, L. tropidonotum; 59, L. uyacicola; 60, L. zonulum.

Alveolate (Figure 107), "honeycombed"; here used for microscopically honeycombed surfaces that appear dull through the light microscope.

Doubly-punctate (Figure 105), surface with punctures of two distinct sizes.

Granulate, "covered with or made up of very small granules." Granuloso-punctate (Figure 150), fine to coarse contiguous punctation, giving surface a dull, granulate appearance.

Porcate (Figure 127), "with several parallel, longitudinal ridges with deep, broad sulcations."

Reticulate (Figure 130), "superfically net-like or made up of a network of lines."

Rugose, wrinkled.

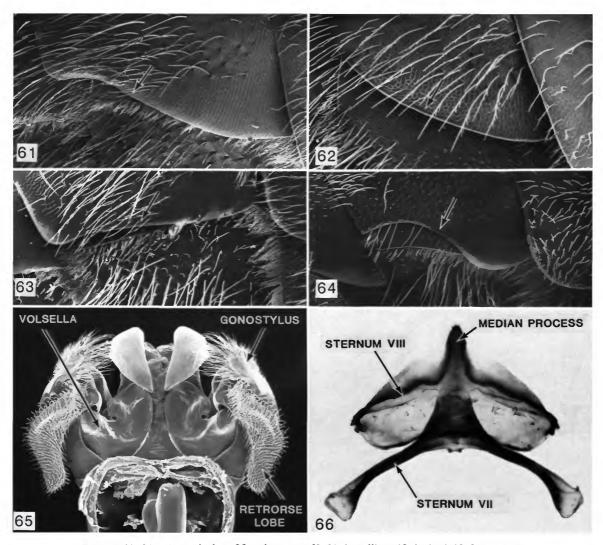

Rugulose (Figure 292), minutely wrinkled.

Ruguloso-striolate (Figure 108), very fine longitudinal lines that are also minutely but noticeably wrinkled.

Scabriculous (Figure 548), minutely scabrous.
Scabrous, "rough; irregularly and roughly rugose."
Striate (Figure 636), "marked with parallel, fine, longitudinal impressed lines or furrows."
Striolate, "minutely or finely striate."

# PHYLOGENY

The phylogeny of New World Lasioglossum species is here treated only in a preliminary manner. This is because the group is holarctic and I have not yet studied the many Old World species that have been reviewed by A.W. Ebmer (see Literature Cited section). Furthermore, we cur-

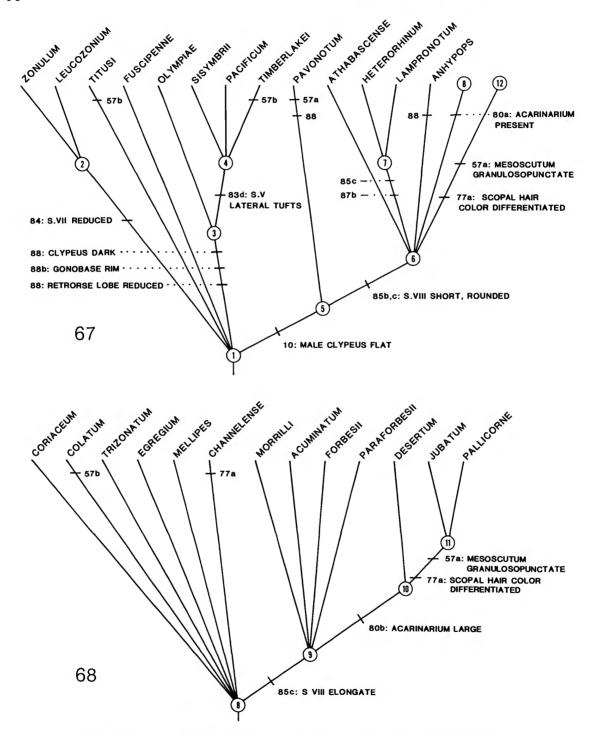

FIGURES 61-64.—Lateral edge of female tergum II: 61, L. mellipes; 62, L. titusi; 63, L. egregium; 64, L. coriaceum.

FIGURES 65, 66.—Male L. athabascense: 65, genitalia, ventral view; 66, sterna VII-VIII.

rently lack even gross estimates of halictine generic interrelationships, which makes character polarity assessments based on outgroup analysis difficult at best. An additional complication is that some of the potential outgroups are certainly paraphyletic and possibly even polyphyletic as presently defined, e.g., *Dialictus*, *Evylaeus*. A rig-

orous study of *Lasioglossum* phylogeny and biogeography is planned after a monograph of New World *Evylaeus* is completed. The present section is intended to provide an introductory basis for these future cladistic studies.

Of the 90 characters utilized for descriptive purposes, only 48 could be confidently coded

FIGURES 67, 68.—Preliminary cladogram for New World Lasioglossum with known males (see text for details).

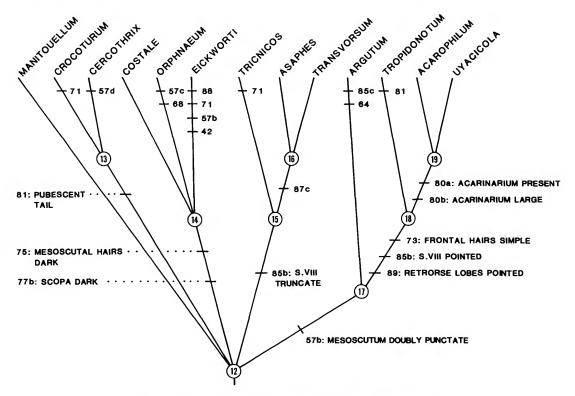

FIGURE 69.—Continuation of cladogram in Figure 67 (see text).

into unambiguous character states. Also, certain details of punctuation and coloration were purposely ignored when intraspecific variability appeared to be great. The 48 characters having potential value in phylogenetic studies are listed below and discussed in relation to the cladogram presented in Figures 67-69. This cladogram is based on an analysis of 26 characters (indicated below with an asterisk) that are associated with what appear to be unique or near unique states within the Halictinae and therefore confidently polarized (apparent apomorphic character states are presented in small capital letters). Because of the great number of male characters involved, species for which males are still unknown were excluded from initial cladogram construction (possible relationships of these species are discussed below).

The cladogram was constructed with the aid of the PHYSYS program (copyright 1983 by J.S.

Farris and M.F. Mickevich); a Wagner Ground-Plan Analysis was performed and the branch-swapping option utilized. In the following character listing, the first character number is that which is utilized throughout the text; the second number (in parentheses) corresponds to the associated matrix character number in Appendix 1.

- 1(1). Female body size: (1) small to moderate, under 9 mm; (2) conspicuously large, 9–12 mm. Among New World species, the conspicuously large body size is characteristic of L. eickworti, L. katyae, and L. sandrae.
- 4(47). Female head: (1) elongate; (2) conspicuously short. Head length varies considerably among species but may prove to be a difficult character to code for phylogenetic studies. Long heads are characteristic of nodes 2, 16, and 18; short heads support nodes 3, 7, 10, 14.
- \*8(2). Female supraclypeal area: (1) moderately protuberant, rounded; (2) STRONGLY PROTUBERANT,

- NARROWLY ROUNDED. The apomorphic state is found only in L. eickworti, L. katyae and L. sandrae.
- \*10(3). Male clypeal surface: (1) rounded; (2) FLATTENED. The flattened and highly polished male clypeal surface appears to be unique for most New World Lasioglossum species and strongly supports node 5. The clypeus of other male halictines is rounded and dull or distinctly punctate.
- 24a(4). Distal process of male labrum: (1) absent or weakly developed; (2) well developed.
- 24b(6). Distal process of male labrum: (1) at most, moderately projecting; (2) sharply projecting, needle-like.
- 26(6). Basal lateral depressions on male labrum: (1) absent; (2) present. These labral depressions are widespread throughout the genus but are especially common among Mexican species. Among species at node 12 the depressions are absent only in L. transvorsum.
- 27(7). Distal keel of female labrum: (1) narrow to moderately broad; (2) conspicuously wide, spatulate. The spatulate distal keel is found primarily among Mexican species and supports nodes 16, 10 (excluding L. pallicorne). It is also possessed by L. argutum and L. bajaense, a potential sister-species relationship indicated by other characters.
- 28(8). Distal lateral projections of female labrum: (1) present; (2) absent or greatly reduced. The reduction to near absence of the distal lateral projections is characteristic of the species at node 3 and L. fuscipenne and L. orphnaeum (it is also reduced in L. aequatum, L. circinatum, L. tropidonotum, and L. xyriotropis).
- 30(9). Male mandible: (1) short, obviously shorter than distance to opposing clypeal angle; (2) subequal to distance to opposing clypeal angle; (3) elongate, obviously exceeding distance to opposing clypeal angle. Extremely short mandibles are found among node 3 species as well as L. pavonotum. Conspicuously elongate mandibles are found throughout the genus, including L. orphnaeum, L. eickworti, and node 7 species.
- 32(10). Pronotal lateral angle: (1) obtuse, weakly projecting; (2) acute, sharply projecting. The sharply projecting pronotal angle is found in L. eickworti, L. katyae, and L. sandrae; L. orphnaeum and L. perscabrum (a sister-species relationship also suggested by character 57c), as well as L. citerius and L. zonulum.
- 33(11). Pronotal lateral ridge: (1) obviously interrupted by lateral sulcus; (2) complete or only inconspicuously interrupted. This character varies greatly among *Lasioglossum* species and within related potential outgroup genera. Among those species hav-

- ing a complete ridge are those at nodes 7 and 16; L. orphnaeum and L. perscabrum; L. pallicorne and L. parkeri.
- 34(12). Lower portion of pronotal lateral ridge: (1) sharply edged; (2) broadly rounded, inconspicuous. The broadly rounded lower ridge is found in all species below node 6. Among New World species this condition is found elsewhere only in *L. citerius* and *L. colatum*.
- 40(13). Dorsal propodeal surface: (1) longer than metanotum, subequal to scutellum in length; (2) conspicuously short, subequal to metanotum in length, shorter than scutellum. The very short propodeum is found in *L. leucozonium* and *L. zonulum* (node 2) and *L. titusi*.
- \*42(48). Dorsal propodeal surface: (1) rounded or truncated; (2) NARROWLY ROUNDED. The noticeably elongate and narrowly rounded propodeal surface is apparently unique to *L. eickworti*, *L. katyae*, and *L. sandrae*.
- 44(14). Lateral propodeal carinae: (1) weakly developed, not reaching dorsal propodeal surface; (2) well developed, reaching or very nearly reaching dorsal surface. Well-developed lateral carinae are highly correlated with a strongly sculptured propodeal surface, character 63. Strong carinae are present in all species below node 5 (excepting *L. titusi*, where they are still moderately developed and nearly reach the dorsal propodeal surface) as well as *L. aequatum*, *L. citerius*, *L. orphnaeum*, and *L. perscabrum*.
- 45(15). First major tooth of inner tibial spur: (1) at immediate base (distance from base subequal to length of first tooth); (2) intermediate in distance from spur base; (3) over one-third the length of the spur from spur base. Among New World Lasioglossum, the extreme basal positioning of the first spur tooth is found only at node 3; future study may show this to be an apomorphic condition. Also unusual is the extreme distal positioning of the first tooth found in L. forbesii (sensu lato), L. morrilli, L. desertum, L. coriaceum, L. fuscipenne, L. argutum, and at node 7.
- \*57a(16). Mesoscutal punctation: (1) punctures distinct, at least over posterior half; (2) GRANULOSO-PUNCTATE THROUGHOUT. The highly granuloso-punctate mesoscutum is found primarily among Mexican species, that is, all species at nodes 11 and 12 as well as L. pavonotum.
- \*57b(17). Mesoscutum: (1) not doubly-punctate; (2) DIS-TINCTLY DOUBLY-PUNCTATE. The doubly-punctate mesoscutum is found in species at node 17 as well as L. colatum, L. eickworti, L. timberlakei, and L. titusi.

\*57c(18). Anterior portion of mesoscutum: (1) non-scabriculose; (2) SCABRICULOSE. The scabriculose anterior mesoscutal edge is apparently unique to L. orphnaeum and L. perscabrum.

- \*57d(19). Mesoscutal punctation: (1) fine; (2) moderately coarse; (3) CONSPICUOUSLY COARSE. Most New World species have fine mesoscutal punctation. The punctation is moderately coarse in L. leucozonium and L. zonulum and unusually coarse in L. aequatum, L. cercothrix, and L. citerius.
  - 63(20). Dorsal propodeal surface: (1) ruguloso-striolate; (2) striolate; (3) strongly striate or reticulate; (4) smooth over posterior half. As mentioned above, the strongly sculptured propodeum is correlated with the strong development of lateral carinae. The smooth propodeal surface is found among species at node 17 as well as L. bajaense, L. circinatum, and L. pharum (all most likely form a natural grouping). Elsewhere a smooth propodeum is found in L. coriaceum, L. pallicorne, and L. parkeri.
- \*64(21). Posterior half of dorsal propodeal surface: (1) dull, either alveolated or variously sculptured; (2) POLISHED, SMOOTH AND SHINY. Among New World species, the polished propodeal surface is found only in *L. argutum* and *L. bajaense*.
- \*68(22). Male clypeal maculation: (1) present; (2) ABSENT. The clypeal maculation, usually present in male halictines, is absent in species at node 3, *L. orphnaeum*, *L. pavonotum*, and many specimens of *L. anhypops*.
- \*71(23). Forewing membrane: (1) uniformly pigmented, hyaline to lightly pigmented; (2) apex infuscated; (3) ANTERIOR HALF ALONG COSTAL MARGIN INFUSCATED. The infuscated apex is found among several Mexican species, whereas the highly unusual infuscated anterior margin is found in *L. crocoturum*, *L. eickworti*, *L. katyae*, *L. sandrae*, and *L. tricnicos*.
- \*73(24). Frontal hairs below ocelli: (1) plumose, similar to other facial hairs; (2) SIMPLE WITH RECURVED APICES. Simple, recurved frontal hairs are apparently found only among species at node 18 as well as in *L. circinatum* and *L. pharum*. This corroborates the pattern suggested by character 63 (smooth propodeal surface).
- \*75(25). Mesoscutal hairs: (1) white to pale orange; (2) BLACK. Dark mesoscutal hairs are found only among species at node 14 (including *L. katyae* and *L. sandrae*) and *L. citerius*.
- \*77a(26). Color of tibial hairs: (1) uniformly pale; (2) DIF-FERENTIATED, WITH DARK HAIRS ON DORSAL SUR-FACE OR HAIRS ENTIRELY DARK. Differentiated scopal hair color is characteristic of Mexican species, found among all species at node 11 and 12 (sug-

- gesting *L. jubatum* and *L. pallicorne* are misplaced in the preliminary cladogram; also indicated by the entirely granuloso-punctate mesoscutum).
- \*77b(27). Tibial scopa: (1) with at least some pale hairs; (2) ENTIRELY DARK BROWN OR BLACK. Scopa having all dark hairs are found only in L. eickworti, L. katyae, L. sandrae, L. orphnaeum, L. perscabrum, and L. costale.
- \*80a(28). Acarinarium: (1) absent; (2) PRESENT. The acarinarium, apparently absent in Old World species, is present in all species at nodes 8, 19 as well as in *L. bajaense*, *L. bardum*, and *L. parkeri*.
- \*80b(29). Acarinarium: (1) absent to moderate in size; (2) CONSPICUOUSLY LARGE, CIRCULAR. A conspicuously large acarinarium is found at nodes 10, 19 and in *L. bajaense* and *L. bardum*.
- 80c(31). Acarinarium: (1) sharply defined by elongate fringe hairs; (2) indistinctly defined. The indistinctly defined acarinarium is found in *L. trizonatum* (sensu lato) and *L. colatum* at the base of node 8, possibly indicating a natural grouping. Given the extreme similarity of *L. anhypops* to other *trizonatum* forms, its lack of an acarinarium is presumed to be secondary.
- \*81(30). Terga IV-V of female: (1) with normal basal hair bands; (2) ENTIRELY PUBESCENT. The pubescent tail is found at node 13 and in *L. tropidonotum* and *L. sandrae*. This feature along with the infuscated anterior wing margins is presumably associated with polybine mimicry and therefore possibly subject to homoplasy as indicated in the preliminary cladogram.
- 83a(32). Erect, lateral hair tufts on sternum V of male: (1) absent; (2) present.
- 83b(33). Adpressed hair fringes on posterior edge of male sternum V: (1) absent; (2) present.
- 83c(34). Sternum VI of male: (1) lacking distinctive hair patterns; (2) with well-formed, distinctive hair patterns. Among New World species, the vestiture on sternum VI is found only in *L. leucozonium* and *L. zonulum* (node 2).
- \*83d(35). Sternum V of male: (1) without elongate lateral hair tufts; (2) WITH ELONGATE LATERAL HAIR TUFTS. The apparently unique, elongate lateral hair tufts on sternum V provide a strong synapomorphy at node 4.
- \*84(39). Sternum VII of male: (1) well developed; (2) SLENDER, REDUCED. Among New World species, reduction of sternum VII is found only in *L. leucozonium* and *L. zonulum* (node 2).
- 85a(36). Median process of male sternum VIII: (1) present; (2) absent or extremely reduced. The absence of the sternal VIII median process is found in all species below node 5 corroborating the clypeal

morphology pattern (character 10). The median process is also absent in *L. eickworti*.

- \*85b(37). Median process of sternum VIII: (1) rounded; (2) SHARPLY POINTED; (3) A TRUNCATED CONVEXITY AS SEEN IN VENTRAL VIEW. The sharply pointed median process is apparently unique to species at node 18; the unusual truncated condition is found only at node 15.
- \*85c(38). Median process of sternum VIII: (1) absent; (2) SHORT; (3) CONSPICUOUSLY ELONGATE. The very elongate median process is found only at node 9 and in *L. argutum*. Considering the short median process as part of an ordered sequence is tenuous at best and provides only very weak support for node 6.
- 86a(40). Gonobase: (1) short, approximately 0.5 the length of gonocoxite as seen in dorsal view; (2) moderate in length; (3) elongate, subequal to or slightly longer than gonocoxite. The conspicuously short gonobase is found at node 2, node 3 (excepting *L. pacificum*), and in *L. eickworti*. The very elongate gonobase is found primarily among Mexican species and supports node 18.
- \*86b(41). Conspicuous rim at apex of gonobase: (1) absent; (2) PRESENT. The unusual gonobase rim is apparently found only in species at node 3.
- 87a(44). Gonostylus: (1) hairy, with numerous elongate setae; (2) virtually hairless, with only very short, sparse setae. Among New World species, the virtually hairless gonostylus is found only at node 2 and in *L. titusi*.
- \*87b(45). Gonostylus: (1) without basal collar; (2) WITH BASAL COLLAR. The apparently unique gonostylar collar is found only at node 7.
- \*87c(46). Membranous lobe on inner apical surface of gonocoxite: (1) absent; (2) PRESENT. This membranous lobe is apparently found only in *L. asaphes* and *L. transvorsum* (node 16).
- \*88(42). Membranous retrorse lobe on ventral surface of genitalia: (1) well developed; (2) REDUCED; (3) absent. Among New World species the retrorse lobes are completely absent only in *L. leucozonium* and *L. zonulum* (node 2). Whether or not this is plesiomophic for the genus cannot be determined at present. The reductional state is most likely derived and supports node 3 and is also found in *L. eickworti*.
- \*89(43). Membranous retrorse lobe: (1) rounded distally; (2) SHARPLY POINTED DISTALLY. The sharply pointed retrorse lobes provide strong support for node 18.

The resolution of the derived cladogram is not high, as one would expect when clustering 39

taxa on the basis of only 26 characters. However, given the unique to nearly unique nature of the character states involved, the groupings obtained should be of some significance.

In Figure 67, the holarctic species, L. leucozonium and L. zonulum (node 2), form a distinct group that is clearly related to many Old World species. In addition to the unique reduction of the male seventh sternum, this group shares similarities in the following nonordered characters: 40, 57d, 83c, 86a, 87a. Also well supported is the group of species at node 3, all from the western United States and Mexico. Nonpolarized similarities associated with this group involve characters 28, 30, 45 and 86a. The enigmatic position of L. fuscipenne and L. titusi is clearly indicated. Lasioglossum fuscipenne females lack the labral distal projections (character 28) as do node 3 species but the significance of this similarity cannot be determined without study of other halictines.

A potentially significant finding is that the majority of New World Lasioglossum species (node 5) may comprise a monophyletic group. The males of all Old World Lasioglossum species examined have a rounded clypeal surface that is dull and/or conspicuously punctate (similar to that found in other halictine groups). The clypeus of most New World Lasioglossum males is nearly flat to slightly depressed, and polished with only obscure punctation. The clypeus of L. eickworti males is rounded and supposedly shows a reversal for this feature in the present analysis. Another interpretation, discussed below, is that this character supports the hypothesis that L. eickworti, L. katyae, and L. sandrae comprise a natural group (based on other characters) that is only distantly related to other New World species.

Lasioglossum pavonotum, the only metallic New World species, also has highly unusual male genitalia (Figures 592–595). While its obscure phylogenetic position is emphasized in Figure 67, the flat to slightly depressed male clypeus suggests that it belongs to a large New World species group. This species, along with L. eickworti and all other species below node 5, lack the well-

developed median process of the eighth male sternum; however, the cladistic value of this similarity cannot be ascertained without further study of other halictine taxa. Consequently, the presence of a short, rounded median process provides only tenuous support at node 6 (conservatively, node 6 should drop to node 5).

Species at node 6 are distributed into three generalized groups. The first is an unresolved group comprised of Lasioglossum athabascense, node 7 (L. heterorhinum, L. lampronotum), and L. anhypops. These are species from the United States, i.e., species lacking the unusual characters associated with most Mexican species at node 12, that also lack an acarinarium typical of species grouped at node 8. Future work will most likely show some if not all of these species to be related to species in node 8. For example, L. anhypops lacks the acarinarium found in other trizonatum forms but otherwise both groups are virtually identical. The lack of an acarinarium in L. anhypops possibly represents a secondary loss, which can be determined only by further work.

All species at node 8 (Figure 68) are associated with mites and possess an acarinarium at the base of the first abdominal tergum. The naturalness of this grouping is open to question as it most likely excludes such species as L. anhypops (discussed above). Furthermore, the characters supporting node 11 are also characteristic of the Mexican species at node 12, suggesting that the placement of L. jubatum and L. pallicorne is problematic at best. Nevertheless, the unusually elongate median process of the male eighth sternum suggests some naturalness to the grouping at node 9. Interestingly, the species at the base of node 9 (L. morrilli, L. forbesii, sensu lato, L. desertum, as well as L. coriaceum) share the extreme distal placement of the first tibial spur tooth discussed in the treatment of character 45. At the base of node 8, L. colatum, the three trizonatum species, and L. channelense share the indistinctly formed acarinarial hair fringe, which may or may not have phylogenetic significance.

Most species from Mexico and Central America are grouped at node 12 (Figure 69). They are characterized by the densely granuloso-punc-

tate mesoscutum and differentiated scopal hair coloration (as in Figure 1). This group may also include L. jubatum and L. pallicorne (node 11) as mentioned above. Within node 12 only two clades are strongly supported at present. Node 18 is extremely well supported by the sharply pointed median process of sternum VIII and the uniquely pointed retrorse genitalic lobes. The unusual simple and recurved frontal hairs supporting node 18 are also shared by L. circinatum and L. pharum (both Mexican species for which males are yet unknown). Species at node 15 all share the highly unusual median process of sternum VIII, a truncate, semicircular projection (Figure 285). Although the doubly-punctate mesoscutum is not unique to the species at node 17, this pattern is corroborated by the smooth propodeal dorsal surface found in the included species (both features are shared by L. bajaense, L. circinatum, and L. pharum indicating that they too belong here; a further relationship is suggested by L. argutum and L. bajaense having a uniquely polished dorsal propodal surface).

The relationships of other species included at node 12 remain obscure. Node 13 is only weakly supported by the pubescent abdominal apex (character 81), which also occurs in *L. sandrae* and *L. tropidonotum*. Although dark scopal and mesoscutal hairs (characters 75, 77b) are highly unusual in the genus and related groups, this support for the naturalness of node 14 remains unconvincing. In fact, *L. eickworti*, *L. katyae*, and *L. sandrae*, appear to comprise a natural taxon that may only be distantly related to most New World *Lasioglossum* (see "Remarks" section for *L. eickworti* for further details).

### FLORAL ASSOCIATIONS

The Lasinglossum floral associations reported herein are based exclusively on specimen label data that does not differentiate between pollenand nectar-gathering visits. While specimen label data were being recorded, those bees having noticeable pollen loads were noted and their numbers herein indicated parenthetically next to

TABLE 2.—Plant families with more than 35 records of visits by Lasioglossum (number of females
with pollen loads given in parentheses).

the total number of specimens associated with a plant genus or family (a plant taxon associated with pollen-laden bees is preceded by an asterisk in the flower visitation listings for each *Lasioglossum* species). Although the actual source of pollen is not indicated by such records, they nevertheless provide some tenuous information on the subject. In general, specimen label data provide only limited information on floral associations but are here reported to summarize what data presently exist and to compare these with similar data reported for a group of long-tongued bees, the California Bombini (Thorp et al., 1983).

Of the total specimens of Lasioglossum examined, 5348 (21%) had associated floral data. The records were from 317 plant genera representing 74 families. Tables 2 and 3 list those families and genera having 35 or more Lasioglossum records (this is proportional to the 50-visit cut-off for the Bombini data reported by Thorp et al., in which

there were a total of 7437 floral records). Of the 51 New World Lasioglossum species, 39 have associated floral data; nothing is known about the floral associations of 12 species from Mexico and Central America. An additional nine species occurring south of the Mexican border have six or fewer records. The floral summary for Lasioglossum is highly influenced by six species that account for 67% of the total records: L. sisymbrii (22%), leucozonium (15%), paraforbesii (8%), titusi (8%), coriaceum (8%), and zonulum (6%). The male records are highly influenced by two species, L. leucozonium (42%) and sisymbrii (15%).

Figure 70 plots the plant family visitation records reported by Thorp et al. (1983) for California Bombini with comparable data for *Lasioglossum* superimposed (note that this comparison will be highly influenced by the restriction of the Bombini records to the Californian flora, whereas the *Lasioglossum* records are not so lim-

ited). The Compositae constitute 37% of all Lasioglossum floral records, which is similar to the 39% figure reported for the Bombini. This family appears to be especially important for Lasioglossum males, where it accounts for 65% of all records and is probably a reflection of the late summer and fall emergence of most males and

their association with Aster and Solidago. Though the Compositae is the most commonly visited family by both Lasioglossum and Bombini, Figure 71 and Table 3 indicate that different plant genera are involved. The three plant genera most commonly visited by Californian Bombini are Cirsium, Chrysothamnus, and Helianthus (all composites) but appear to be infrequently visited by Lasioglossum. The primary composites reported for Lasioglossum are Solidago (6.5%), Erigeron (2.8%), Taraxacum (2.6%), Aster (2.5%), and Hieracium (2.5%).

The Leguminosae are much less important for Lasioglossum (8.9%) than for the Bombini (19%). Lupinus, Trifolium, and Astragalus, all important plants for the Bombini, appear to be relatively unimportant to Lasioglossum species; Melilotus is the only legume commonly visited by Lasioglossum. Unlike the Bombini, the Rosaceae constitute the second most important plant family recorded for Lasinglossum specimens with visits to Prunus (3.3%) and Rubus (1.7%) especially well represented. The Rosaceae is the most commonly visited family recorded for four Lasinglossum species: L. athabascense, coriaceum, forbesii, and paraforbesii. Two other families with open, shortcorolla-type flowers are relatively more important for the short-tongued Lasioglossum than for the Bombini: Cruciferae (6.3%) and Polygonaceae (Eriogonum, 3.1%). Salix is the second most important plant genus associated with Lasioglossum, visited by 20 of the 39 bee species having floral data. This genus is relatively less important for Bombus, where Salix is visited only by earlyspring foundress queens. The differences between the floral records for California Bombini and North American Lasioglossum, though highly influenced by differences in associated floras, possibly indicate that the short-tongued Lasioglossum species are more commonly associated with the open flowers of the Rosaceae and Cruciferae and are less commonly associated with the zygomorphic flowers of the Leguminosae and Labiatae, both important families for the longtongued Bombini. Although the Compositae appears to be of primary and nearly equal importance to both groups of bees, different composite

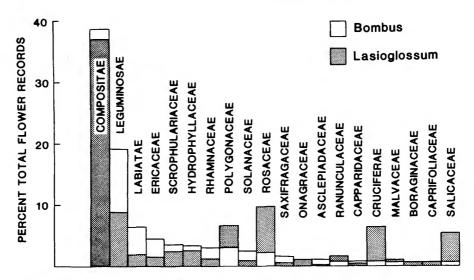

FIGURE 70.—Comparison of flower records (plant families) for New World *Lasioglossum* and California Bombini (Bombini data from Thorp et al., 1983).

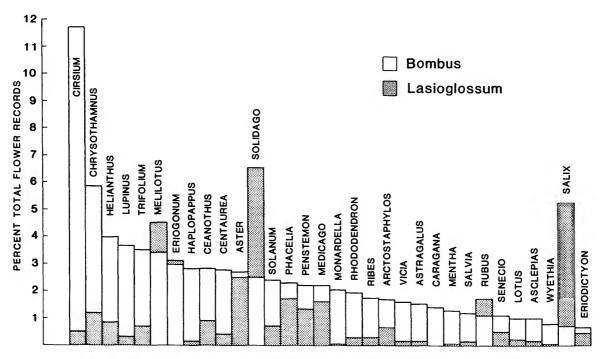

FIGURE 71.—Comparison of flower records (plant genera) for New World Lasioglossum and California Bombini.

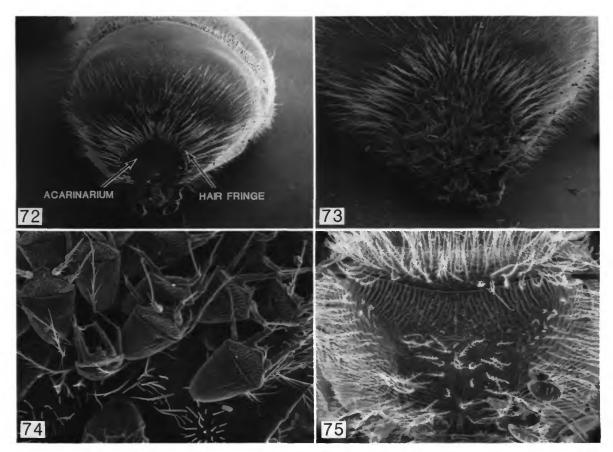

genera are represented in known records for both bee taxa.

Lasioglossum flower records and a review of those females with noticeable pollen loads indicate that nearly all species are broadly polylectic. One exception is L. titusi, which is possibly broadly oligolectic, apparently collecting pollen only from the Compositae. Lasioglossum leucozonium records also indicate some preference for composite pollen, but this is less well supported than is the case for L. titusi oligolecty (see individual species accounts for further details).

## MITE ASSOCIATIONS

As reviewed by Eickwort (1979), the association of many halictid bees with nest-inhabiting

mites is one of the more interesting aspects of halictid biology. In most cases involving Lasioglossum species, deutonymphal mite hypopodes attach to an acarinarium on the anterior surface of the first abdominal segment of the developing female bee (Figure 72). The acarinarium often becomes completely filled by overlapping mites as in Figures 73, 74. After the bee emerges and begins provisioning its own nests, the phoretic mites transfer onto the provision masses in the new nest cells. Within the new cells the hypopodes complete their development into adults and the cycle repeats. To date, 15 genera in six families of mites have been associated with halictid bees. Biologies are equally variable and include forms that feed on fungi, pollen, and/or

FIGURES 72-75.—Lasinglossum species and phoretic mites: 72, L. coriaceum abdomen showing empty acarinarium; 73, L. coriaceum acarinarium with mites; 74, close-up of mites in acarinarium; 75, L. titusi with mites clinging to propodeal hairs.

surface fluids on the provision masses or larval bees.

While Lasioglossum specimens were being recorded for this study, it was noted whether or not individual bees had phoretic mites on them. The resulting data are presented in Table 4. Twenty-two of the 51 New World Lasioglossum species were associated with mites (I have not observed an acarinarium or mites on any Old World Lasioglossum, including the holarctic L. leucozonium and L. zonulum).

All of the mites associated with Lasinglossum belong to the family Histiostomatidae (previously Anoetidae), with the exception of Imparipes vulgaris Delfinado and Baker (Scutacaridae) associated with L. titusi (Linsley and MacSwain, 1959; Delfinado and Baker, 1976; Eickwort, 1979). The adult females of this species cling to the propodeal hairs of the female bee (Figure 75) and in cases of heavy infestation cling to hairs on other parts of the thorax, including the front coxae, and less commonly on the genae and anterior surface of the first metasomal tergum (the hairs on this surface are unusually elongate). This is quite different from the situation in Lasioglossum species associated with histiostomatid mites in which the hypopodes attach to an acarinarium on the anterior surface of the first tergum. Hypopodes on male L. titusi are also found on the propodeum and less commonly on the sides of the pronotum, differing from the usual positioning of mites on the venter of the thorax, the forecoxae, and the genae of males of other mite-associated Lasioglossum (a position that would presumedly facilitate the transfer of mites from male to female bees during copulation).

Linsley and MacSwain (1959) reported that in a sample of 50 females of *L. titusi*, 45 (90%) carried hypopodes (reported as acarids). In this study, 1350 females from museum collections were examined and 870 (66.2%) had mites on them (34.2% of the males carried mites). The higher infestation reported by Linsley and MacSwain is probably better indicative of the

TABLE 4.—Number of *Lasioglossum* specimens, by species, associated with phoretic mites.

true level of mite association among young females than are data from museum specimens. As females age they apparently lose most if not all of their phoretic hypopodes, presumably through transfer of the mites onto new provision masses. The lower infestation among museum specimens would reflect this age-attrition factor.

For most of the Lasioglossum species having well-developed acarinaria, the infestation levels of females range from a low of 49.1% (L. acuminatum) to over 80% (L. egregium, L. pallicorne). Species having lower infestation levels fall into three groups. First there is L. bardum, jubatum, and uyacicola, all of which have well-developed acarinaria but are known from so few specimens that comparative figures are virtually meaningless. The availability of more specimens would most likely reveal infestation levels comparable

to the above species. In the second group, L. colatum and pavonotum, the acarinaria are very weakly developed (Figures 351, 591). Although the infestation levels are correspondingly low (6.8% and 10.4%), the males of both species also carry mites and the association of these bees with mites appears to be normal though relatively uncommon. In the third group the association with mites appears to be accidental: the acarinarium is entirely lacking and mites are only rarely found on female bees and never on males. For example, three species of the closely related trizonatum group have well-developed acarinaria and are usually associated with phoretic mites (infestation levels range from 72% to 82%). The fourth species of the trizonatum group, L. anhypops, lacks an acarinarium, and only 15 (2.7%) of the 613 females examined had mites on the first tergum (none of the 262 L. anhypops males carried mites). It is possible that the occurrence of mites on these females may be on account of transfer of hypopodes during attempted matings by infested males of other sympatric trizonatum species.

Samples of *Lasioglossum*-associated mites were removed and sent to B. OConner (University of Michigan) for further study and identification. It is hoped that a future publication will address what, if any, specificity exists between mite and *Lasioglossum* species and possible phylogenetic implications.

# Lasioglossum Curtis

Lasioglossum Curtis, 1833, folio 448 [type-species: Melitta xanthopus Kirby, by monotypy and original designation (= Lasioglossum tricingulum Curtis)].

Curtisapis Robertson, 1918:91 [type-species: Halictus coriaceus Smith, by original designation].

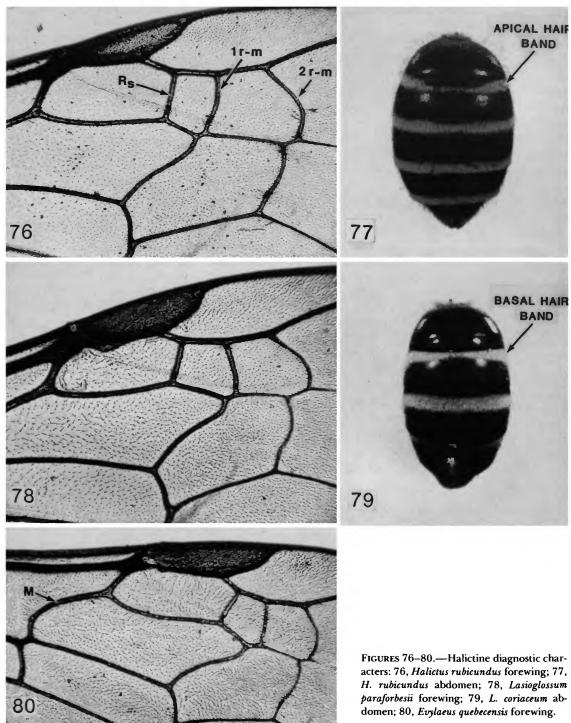

#### DIAGNOSIS

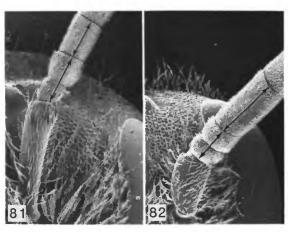

Halictine bees can be recognized by the strongly arcuate basal vein (vein M) of the forewing (Figure 80). Among New World halictine females, the outer wing veins (2 r-m, 2 m-cu, Figure 76) are noticeably weakened only in spe-

cies of Lasioglossum, sensu lato (includes Dialictus, Evylaeus, and the less common Habralictellus, Hemihalictus, Paralictus, and Sphecodogastra; see Michener, 1944:250). The basal hair bands on the abdominal terga (Figure 79) will also differentiate the above genera from the superficially similar Halictus, which have apical tergal hair bands (Figure 77) and well-developed distal wing veins (Figure 76).

Females of Lasioglossum, sensu stricto, differ from Dialictus and Evylaeus in having only the 2 r-m vein weakened (Figure 78), whereas the latter genera and related forms have vein 1 r-m also weakened (Figure 80). Furthermore, Lasioglossum (sensu stricto) females are relatively large bees (specimens examined in the present study ranged from 6.8 to 11.9 mm in length); most Dialictus and Evylaeus are only 4 to 7 mm long; however, a few Evylaeus are as large as 8 to 9 mm, e.g., E. cinctipes and E. robustus). In addition to the above venational difference and smaller size, the dull metallic coloration of the head and thorax will easily separate Dialictus from the normally black Lasioglossum (L. pavonotum is metallic blue-green but is a moderate-sized bee (7.3-9.1 mm, n = 15) occurring only along the Pacific coastline, Figure 583).

The above-mentioned venational differences are subtle among males and commonly results in confusion between Lasioglossum and Evylaeus. Males of the latter genus generally have relatively elongate antennae with the fourth antennal segment longer than segments 2 and 3 combined (Figure 82; fourth segment subequal to segments 2-3 in Lasioglossum, Figure 81). Evylaeus males having short antennae can usually be recognized by their relatively small body size, e.g., E. glabriventris (approximatey 4-5 mm in length). Another useful differentiating feature is clypeal shape: all New World Evylaeus males and only some Lasioglossum have a rounded, protuberant clypeal surface (Figure 445); however, most New World Lasioglossum males have a distinctively flattened to slightly depressed clypeal surface (Figure 435).

FIGURES 81, 82.—Lasioglossum and Evylaeus male antennae: 81, L. coriaceum, comparing length of antennal segments 2-3 to segment 4; 82, Evylaeus sp.

## DESCRIPTION

In the following generic description, characters that vary considerably among New World Lasioglossum species are presented in capital and/or lowercase letters, with the range of character variation presented. Characters thought to be nonvariant for the treated species are given in small capital letters; however, some characters that vary in few species are also printed in small capitals, with the few exceptions listed parenthetically. The identifying character numbers are the same that are used in the species descriptions.

FEMALE.—(1) Length 6.8–11.9 mm; (2) wing length 1.9–3.4 mm; (3) abdominal width 1.8–3.5 mm.

Structure: (4) Head short to elongate; length/width ratio 0.74–1.04. (5) GENA SUBEQUAL TO EYE IN WIDTH, (6) ROUNDED POSTERIORLY, NOT PRODUCED OR ANGULATE. (7) Supraclypeal area evenly to narrowly rounded, (8) very weakly to strongly protuberant. (9) Clypeus projecting approximately 0.64 to all of its length below lower margin of eyes, (10) SURFACE USUALLY BROADLY ROUNDED (somewhat flattened dorsally in L. titusi, L. athabascense; slightly protuberant along ventral edge in L. colatum; with distinct semicircular depression on ventral edge in L. sandrae);

(11) clypeal surface with or without median longitudinal sulcation. (12) FRONTAL CARINA USU-ALLY WELL DEVELOPED, EXTENDING AT MOST TO MIDPOINT BETWEEN ANTENNAE AND MEDIAN OCELLUS (very weakly developed in L. pacificum, L. timberlakei). (13) DISTANCE BETWEEN LATERAL OCELLUS AND EYE GREATER THAN DISTANCE BE-TWEEN LATERAL OCELLUS AND HIND MARGIN OF VERTEX (L. zonulum is the only exception in having these distances subequal or the latter distance exceeding the first); (14) distance between lateral ocelli exceeding, subequal to or exceeded by distance between lateral ocellus and eye; (15) LATERAL OCELLI JOINED ABOVE BY WEAK TO DIS-TINCT IMPRESSED LINE (apparently absent only in L. uyacicola, L. circinatum, L. tropidonotum). (16) COMPOUND EYES CONVERGING VERY SLIGHTLY BE-LOW. (17) HYPOSTOMAL CARINA WELL DEVELOPED AND UNIFORM (conspicuously developed in L. fuscipenne); (18) ANTERIOR ANGLE NARROWLY TO BROADLY ROUNDED, (20) ANTERIOR CARINA NEARLY PERPENDICULAR TO LONGITUDINAL CAR-INA (distinctly rounded and narrow in L. zonulum). (21) SCAPE REACHING TO TOP OF VERTEX; (22) PEDICEL SLIGHTLY LONGER THAN WIDE, SLIGHTLY LONGER THAN FLAGELLOMERE 1; (23) flagellomere 1 shorter than, subequal to, or longer than flagellomere 2. (24) LABRUM WITH BASAL AREA AND DISTAL PROCESS; (25) BASAL ELEVATION WELL DEVELOPED (weakly developed only in L. pavonotum); (26) BASAL LATERAL DEPRESSIONS ABSENT (present only in some males); (27) distal keel narrow, parallel-sided to very broad and spoon-shaped as seen in frontal view; (28) distal lateral projections conspicuously developed to absent; (29) fimbrial setae all acutely pointed or bluntly rounded distally. (30) MOUTHPARTS NOT UNUSUALLY MODIFIED OR ELONGATE; (31) MANDIBLE WITH DISTINCT SUBAP-ICAL TOOTH.

(32) Pronotal lateral angle broadly obtuse, narrowly obtuse, or forming a sharply pointed, projecting right angle; (33) pronotal lateral ridge complete or interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge broadly rounded to sharply edged. (35) Mesoscutal lip

rounded to strongly bilobed, (36) strongly to very weakly elevated from pronotum; (37) MEDIAN MESOSCUTAL LINE GENERALLY WEAKLY IM-PRESSED TO ABOUT HALF LENGTH OF MESOSCUTUM (very weakly impressed in L. titusi; extending beyond mesoscutal midpoint in L. leucozonium, L. olympiae, L. pacificum, L. timberlakei, L. sisymbrii, L. zonulum); (38) PARAPSIDAL LINES ABOUT 0.29-0.43 LENGTH OF MESOSCUTUM. (39) MEDIAN SCUTELLAR IMPRESSION VERY WEAK (absent in L. leucozonium, L. zonulum, L. titusi, L. bajaense). (40) Dorsal surface of propodeum about 0.53-0.95 the length of scutellum and slightly shorter than to 1.7 times the length of metanotum, (41) depressed or not depressed centrally, (42) posterior margin rounded to sharply truncated; (43) propodeal triangle inconspicuous to moderately well defined, median V-shaped area inconspicuous to strongly elevated, lateral rims of propodeal dorsal surface present or absent; (44) lateral carinae well developed and encircling posterior propodeal surface to weakly developed and extending no more than one-third distance of posterior surface. (45) Tibial spurs as in Figures 14-60.

(46) Lateral edge of metasomal tergum II straight to strongly sinuate.

Sculpture: (47) Face shiny or dull, (48) densely and usually contiguously punctate below ocelli, area between ocelli and antennae uniformly punctate or punctures becoming larger and less dense near antennae; frons of some Mexican species doubly-punctate. (49) VERTEX DENSELY PUNCTATE NEAR EYE, PUNCTURES SEPA-RATED BY THEIR DIAMETER OR LESS (vertex near eye of L. titusi highly polished, doubly-punctate, smaller punctures very fine, inconspicuous, separated by their width, larger noticeable punctures separated by about two times their width); (50) VERTEX BEHIND OCELLI USUALLY OBSCURELY PUNCTATE WITH OBSCURE TRANSVERSE STRIA-TIONS (striations conspicuous only in L. leucozonium). (51) Supraclypeal area polished, granulate or strigulate, (52) densely to sparsely punctate. (53) Clypeus polished or granulate; (54) punctation variable. (55) HYPOSTOMA OBSCURELY STRIOLATE TO STRONGLY STRIATE, OFTEN POL-ISHED LATERALLY, PUNCTURES USUALLY OBSCURE AND SPARSE (sculpture of this area shows high levels of intraspecific variation).

(56) Mesoscutum shiny or dull; (57) punctation variable, sparse to granuloso-punctate, doublypunctate in some species. (58) Scutellar punctation variable, uniform and similar to that of mesoscutum or finer and less dense, often with very sparsely punctate to impunctate areas adjacent to median line. (59) METANOTUM GRANU-LATE TO RUGULOSE, PUNCTATION USUALLY OB-SCURE. (60) PRE-EPISTERNUM USUALLY RUGULOSE (rugose in L. leucozonium, L. zonulum); (61) HY-POEPIMERAL AREA AND MESEPISTERNUM USUALLY RUGULOSE TO ROUGHLY STRIGULATE (strigate in L. leucozonium, rugose in L. zonulum, granulosopunctate in L. crocoturum, L. tricnicos), USUALLY WITHOUT DISTINCT PUNCTURES (present only in L. crocoturum); (62) UPPER PORTION OF METEPIS-TERNUM USUALLY STRIGULATE, BECOMING GRAN-ULATE BELOW (entirely strigate in L. fuscipenne, L. leucozonium, L. titusi, L. zonulum, L. pacificum, and related species). (63) Dorsal surface of propodeum highly variable in sculpture: smooth, rugulose, ruguloso-striolate, striolate, striate or scabrous; (64) surface smooth or microscopically alveolated.

(65) Metasomal tergum I shiny to dull; (66) punctation moderately fine to extremely fine and obscure, punctation sparse (punctures up to four times their width apart) to granuloso-punctate.

Coloration: (67) HEAD, THORAX, ABDOMEN USUALLY DARK BROWN TO BLACK (metallic bluegreen only in L. pavonotum with tints of metallic blue, purple, or red on mesoscutum and scutellum). (68) CLYPEUS WITHOUT MACULATION (maculation present or absent in males). (69) FLAGELLUM ENTIRELY DARK (ventral surface lightly pigmented in some males).

(70) TEGULAE USUALLY LIGHT BROWN TO BLACK WITH TRANSPARENT ANTERIOR EDGE (pale-translucent in *L. sisymbrii*). (71) Wing membrane hyaline, pale yellowish brown or pale orange; anterior edge and/or apex of forewing infuscated in some species; WING VEINS AND STIGMA LIGHT

TO DARK BROWN. (72) Legs usually dark brown to black (pale ferruginous in some forms of *L. fuscipenne*, *L. mellipes*, most forms of *L. lampronotum*, and all *L. channelense*).

Vestiture: (73) Pubescence of head between vertex and antennae usually plumose or with some inconspicuous hairs near ocelli (this area in L. acarophilum, L. circinatum, L. tropidonotum, L. pharum, and L. uyacicola is covered with simple, distally recurved hairs that contrast with the plumose hairs near antennae; hairs in L. tropidonotum conspicuously thick and pigmented); (74) hairs white to dark brown.

(75) Pubescence of thorax white to dark brown; (76) mesoscutal hairs sparse, simple, inconspicuous to dense and conspicuously plumose. (77) Hind tibial hairs concolorous (white to dark brown) or with color differentiated (dorsal hairs brown, contrasting with relatively pale lateral and/or ventral hairs).

(78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga 11–IV white, yellowish white or yellow. (80) Acarinarium (glabrous area surrounded by elongate hair fringe) on anterior surface of tergum I present or absent. (81) Basal hair bands on terga I1–IV usually present and covering basal one-third of tergum (variously reduced or lost; *L. sisymbrii* with basal hair band on tergum I; terga IV–V entirely covered by short hairs in *L. cercothrix*, *L. tropidonotum*, *L. crocoturum*).

MALE.—Similar to female except as follows: (1) length 6.2–10.1 mm; (2) wing length 1.6–2.9 mm; (3) abdominal width 1.6–2.9 mm.

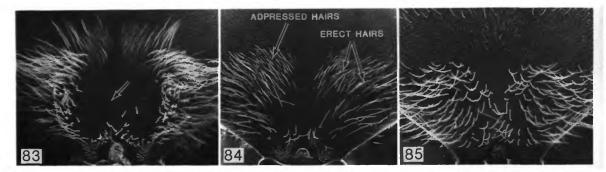

Structure: (4) Head length/width ratio 0.76–1.09. (5) Gena narrower, subequal to, or broader than eye, (6) rounded to strongly produced pos-

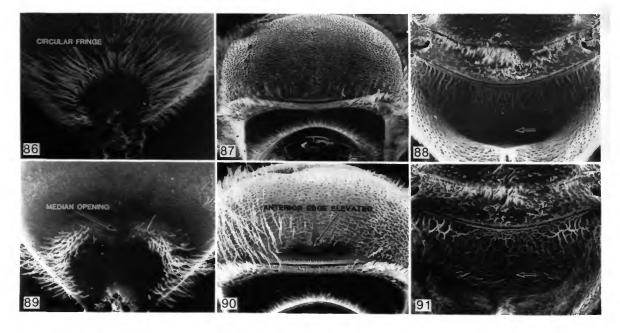

teriorly (with conspicuous angulate projection in L. eickworti). (10) Clypeal surface flat to broadly rounded, ventral edge often shallowly to deeply depressed. (23) FLAGELLOMERE 1 USUALLY SLIGHTLY MORE THAN HALF TO THREE-QUARTERS THE LENGTH OF FLAGELLOMERE 2 (ratio 1:2, approximately 0.53-0.75); flagellomere 1 unusually short in L. sisymbrii (0.45), relatively long in L. titusi (0.87), L. asaphes (0.90), L. transvorsum (0.91). (24) Distal process of labrum present or absent, at most developed into a flat, acute projection; (25) basal area of labrum depressed medially or evenly rounded; (26) basal lateral depressions present or absent; (27, 28) UNLIKE FEMALES, DISTAL KEEL AND DISTAL LATERAL PRO-JECTIONS ABSENT. (30) Mandible very short (not reaching opposing clypeal angle) to conspicuously elongate (reaching opposing mandibular base); (31) MANDIBLE SIMPLE, SUBAPICAL TOOTH ABSENT.

Vestiture: (82) Sterna IV and (83) V with variable vestiture, hairs forming erect tufts, fringes along posterior sternal edge or hairs inconspicuous.

Terminalia: (84) STERNUM VII SIMILARLY SHAPED IN MOST SPECIES (as in Figure 66; varying mostly in width of median process; somewhat reduced, slender in L. leucozonium, L. zonulum); (85) sternum VIII with or without median process, shape of process variable. (86) Gonobase short to elongate; (87) gonostylus variable in size and shape; (88) RETRORSE MEMBRANOUS LOBE USUALLY PRESENT (absent only in L.leucozonium, L. zonulum), (89) size and shape of lobe variable; (90) volsella variable in shape as illustrated, with or without prominent lateral lobe.

### Key to Lasioglossum Females North of the Mexican Border

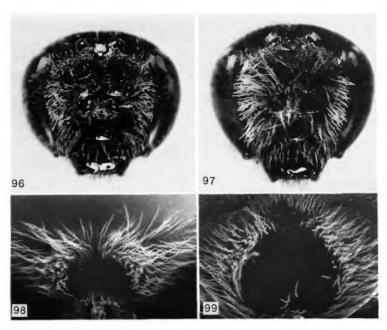

4(3).	Dorsal acarinarial opening very narrow, opening distinctly narrower than width of lateral
	hair fringe as seen in dorsal view [Figure 92]5
	Dorsal acarinarial opening broad to very broad, opening as wide or wider than lateral hair
	fringe [Figure 93]

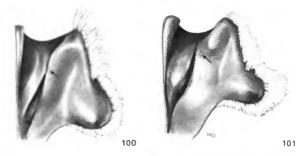

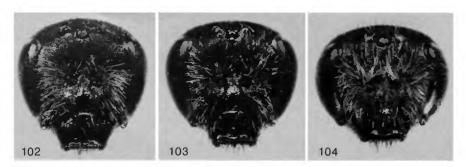

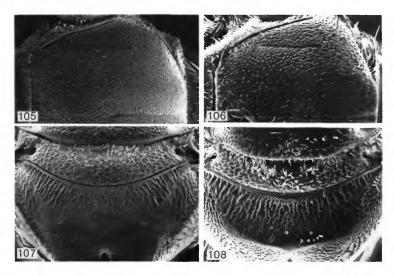

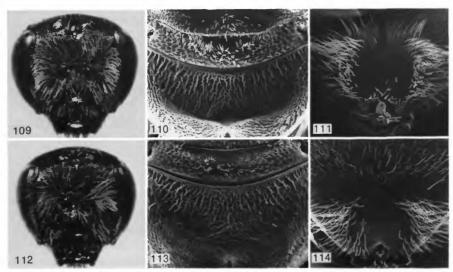

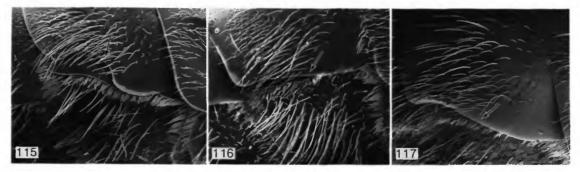

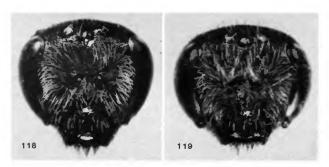

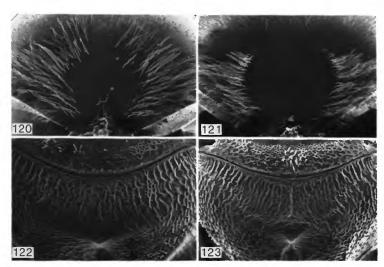

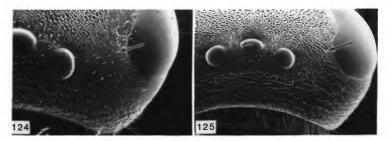

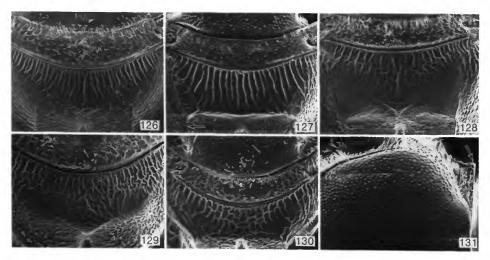

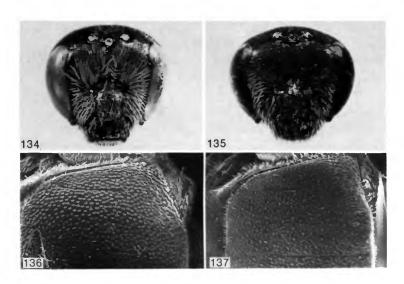

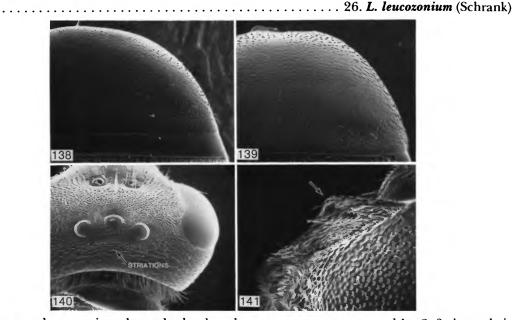

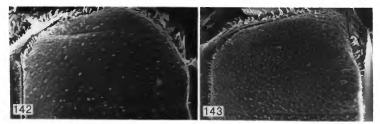

19(18). Dorsal surface of propodeum not strongly sculptured [Figure 128], most striae not reaching posterior margin of dorsal surface; lateral rims of propodeal triangle low but distinct, enclosing a ruguloso-striolate surface that sharply contrasts with smooth propodeal surface laterad of triangle [Figure 128]; mesoscutal punctation nearly uniform, most punctures

separated by a distance greater than their diameter [Figure 131]; metasomal terga conspicuously cloudy, not polished; pronotal lateral angle a sharply projecting right angle [Figure 131]; a species of the eastern states, found west to Kansas and Oklahoma [Figure Dorsal propodeal surface strongly sculptured [Figures 127, 130], striae and rugae reaching posterior margin of dorsal surface; propodeal triangle weakly defined, surface inside and laterad of triangle not contrasting in sculpture; mesoscutal punctation noticeably more dense anteriorly with most punctures separated by the width of their diameter or less [Figures 613, 739] (punctures obscurely formed in L. timberlakei [Figure 622]); metasomal terga polished; pronotal lateral angle a sharply projecting right angle or rounded and 20(19). Tergum I with complete basal hair band, hairs white, short and adpressed [Figure 132]; tegulae translucent, yellow; a western species, found east to Colorado and Texas [Figure Tergum I without basal hair band [Figure 133]; tegulae brown (yellowish brown in some 

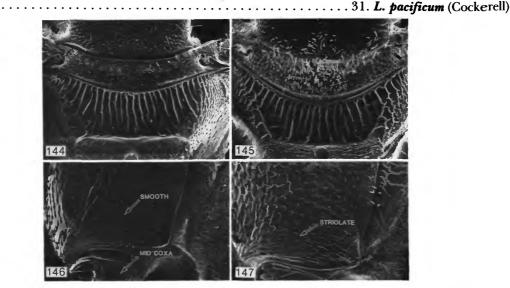

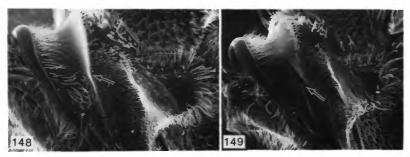

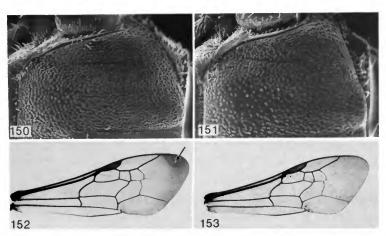

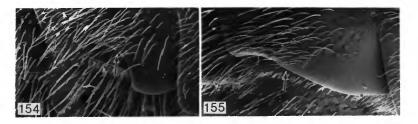

Posterior propodeal margin slightly bowed posteriad [Figure 145]; striae of dorsal propodeal surface relatively less dense [Figure 145]; surface immediately dorsoanteriad of middle coxa dull, striolate [Figure 147]; pubescence generally yellowish brown to golden .....

1. Acarinariu	ım (glabrous	area surroun	ided by elonga	te fringe hair:	s) present on an	iterior surface
of tergu	m I [Figures	156, 157].				2
Acarinariu	ım absent, e	longate hairs	scattered over	anterior sur	face of tergum	I [Figure 85]
						9

	Mesoscutal pubescence white to yellowish white, concolorous with pubescence of pleuron; pronotal lateral ridge incomplete, obviously interrupted by oblique lateral sulcus (as in [Figure 10])
7(5).	Posterior half of dorsal propodeal surface polished and shiny (as in [Figure 266]); supraclypeal area and basal half of clypeus shiny; from Baja California [Figure 300]
	Posterior half of dorsal propodeal surface alveolate and dull [Figure 165]; supraclypeal area dull, conspicuously granulate; species not known to occur in Baja California [Figures 245, 372]
8(7).	Mesoscutum appearing entirely granuloso-punctate, obscurely doubly-punctate (larger punctures more noticeable with SEM than with light microscope), smaller punctures relatively coarse and contiguous on anterior half of disc [Figure 168]; from southern Arizona south to Honduras [Figure 245]
	168
9(1).	Posterior half of dorsal propodeal surface smooth, appearing dull (microscopically alveolated) or highly polished [Figure 170]
	170
10(9).	Posterior half of dorsal propodeal surface highly polished, not alveolated [Figure 170]; head short [Figure 172]; pronotal lateral ridge complete (as in [Figure 9])
	Posterior half of dorsal propodeal surface dull, microscopically alveolated [Figure 165]; head elongate [Figures 173, 601]; pronotal lateral ridge incomplete, distinctly interrupted by
	oblique lateral sulcus (as in [Figure 10])11

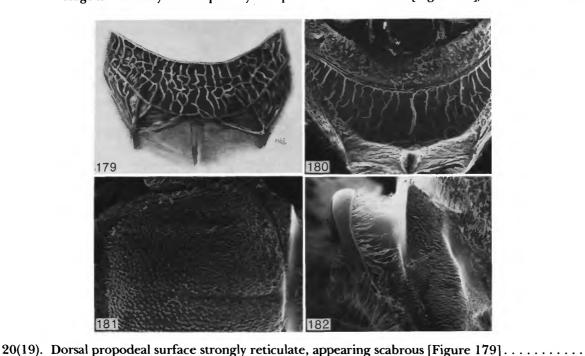

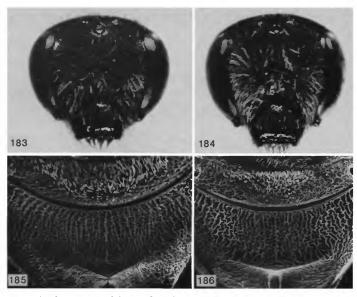

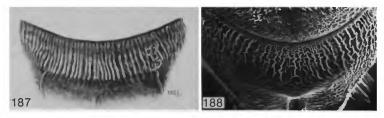

13(9).	Anterior one-third of forewing along costal edge infuscated, contrasting with hyaline poste-
	rior two-thirds [Figure 177]; some species very large (body length: $\bar{x} = 10.0-10.5$ mm)
	with elongate, narrowly rounded dorsal propodeal surfaces14
	Anterior one-third of forewing not infuscated along costal edge, some species with infuscated
	apices [Figure 178] or with entire forewing orange; all smaller species (body length: $\bar{x}$ =
	7.5-9.6 mm) with relatively short, broadly rounded or posteriorly truncated dorsal
	propodeal surfaces [Figures 186, 187] (posterior margin acutely pointed in L. transvorsum
	[Figure 185])

14(13). Terguin III with two transverse, pare pubescent han bands [rigure 1]
15. <i>L. crocoturum</i> (Vachal
Tergum 111 with usual basal hair band [Figures 132, 133]
15(14). Small species (body length 8.4–9.0 mm); anterior surface of tergum 1 with scattered, elongate hairs; pronotal lateral angle rounded, weakly projecting; upper portion of pronotal lateral ridge narrowly rounded, not carinate or flanged
Large species (body length 9.5–11.9 mm); anterior surface of tergum 1 with short, adpressed laterally directed hairs; upper portion of pronotal lateral ridge strongly carinate and flanged near oblique lateral sulcus [Figure 405]
16(15). Mesoscutum covered with short, dense, nearly adpressed pubescence, hairs pale yellowish brown
Mesoscutum with elongate, moderately sparse, erect pubescence, hairs dark brown to black
17(16). Mesoscutal punctation coarsely granuloso-punctate, punctures contiguous
Mesoscutal punctation relatively fine and sparse, punctures separated by their diameter o slightly less, not contiguous
18(13). Tergum I with complete basal hair band [Figure 194]; tegulae translucent, yellow
Tergum I without basal hair band; tegulae brown
19(18). Dorsal propodeal surface strongly reticulate, appearing scabrous [Figure 179] or strongly striate with broad interspaces between striae [Figure 180]; anterior one-quarter of meso scutum scabriculous [Figure 181]; pronotal lateral angle a sharply projecting right angle [Figure 181]; pronotal lateral ridge appearing superficially complete, minutely interrupted by oblique lateral sulcus [Figure 182]; mesoscutal hairs brown to dark brown
by oblique lateral suicus [Figure 102], illesoscutal liaits of owli to dark of owli

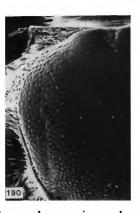

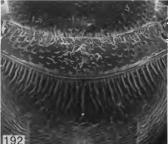

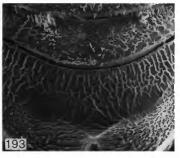

#### Key to Lasioglossum Males North of the Mexican Border

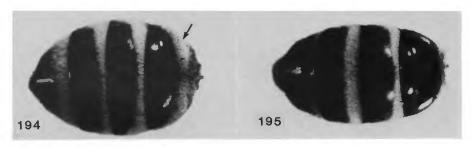

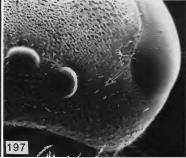

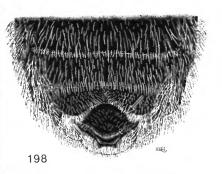

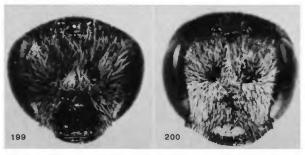

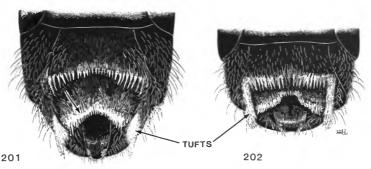

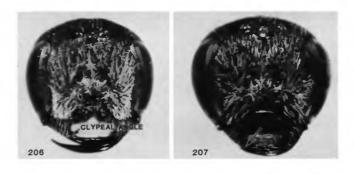

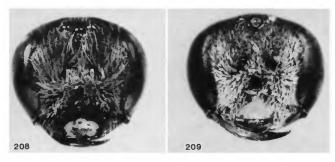

Hind basitarsus yellow to yellowish orange12
Hind basitarsus dark brown14
Pronotal lateral ridge incomplete, obviously interrupted by oblique lateral sulcus (as in
[Figure 10]); northeastern states and eastern Canada, west to Minnesota and Alberta
[Figure 406]
Pronotal lateral ridge appearing complete, at most, minutely interrupted by narrow sulcus
[Figure 100]; southwestern and western United States [Figure 485]
Head moderately elongate, appearing at least as long as broad ([Figure 208], length/width
ratio 0.88-0.96); sternum V with erect, elongate hair tufts [Figure 325]; known only from
California Channel Islands 9. L. channelense, new species
Head short, appearing broader than long ([Figure 209], length/width ratio 0.82); sternum
V with inconspicuous, suberect hairs; from mainland southern California, Arizona, Nevada
and Utah [Figure 485]

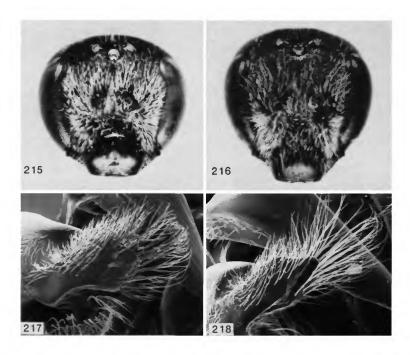

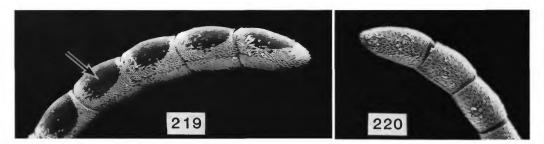

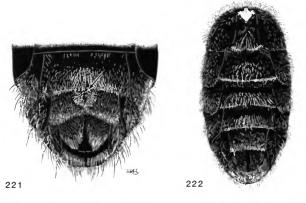

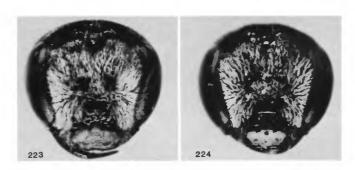

18(17).	Hind tarsus yellowish orange; coastal and cismontane California [Figures 695, 696]
	Hind tarsus dark brown; widespread in western states and Canada to Colorado and Wyoming
	[Figures 682, 708]
19(18).	Antennal flagellomeres with oval tyli (darkened, sharply delimited areas, contrasting with
	rest of flagellomere [Figure 219]); hair tufts on sternum V slightly shorter than those on
	sternum IV 47. L. trizonatum (Cresson)
	Antennal flagellomeres without tyli [Figure 220]; hair tufts on sternum V appearing subequa
	in length to those on sternum IV

21(20). Sternum V with median rosette of elongate, erect hairs [Figure 221]; western species, from Washington, Oregon, and California [Figures 695, 696] . . . . . 46. *L. mellipes* (Crawford) Sternum V without median rosette, hairs short, suberect, not forming noticeable pattern [Figure 222]; eastern species, west to Idaho, Utah, and New Mexico [Figure 406] . . . . 22

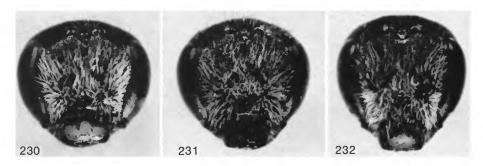

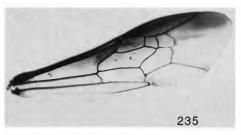

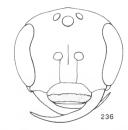

28(27). Head elongate ([Figure 231], length/width ratio 0.87-0.96); clypeal maculation present or absent [Figure 231]; base of clypeus indistinctly rounded . . 44. *L. anhypops*, new species Head conspicuously elongate ([Figure 232], length/width ratio 1.0-1.05); clypeal maculation present [Figure 232]; base of clypeus conspicuously flat . . . . . 47. *L. trizonatum* (Cresson)

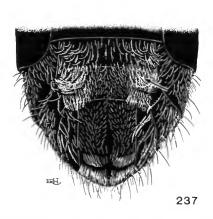

#### Key to Lasioglossum Males South of the Mexican Border

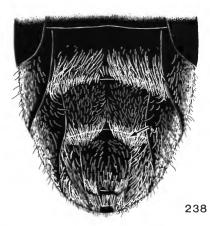

1.	Tergum I with basal hair band, hairs pale, short and adpressed (as in [Figure 194]); dorsal
	propodeal surface striate; tegulae translucent, yellow 39. L. sisymbrii (Cockerell)
	Tergum I without basal hair band; dorsal propodeal surface ruguloso-striolate to striate;
	tegulae yellowish brown to brown2
2(1).	Apex and marginal cell of forewing infuscated [Figure 235]
	Forewing entirely hyaline or, at most, with apex infuscated [Figure 229]
3(2).	Mandibles conspicuously elongate, reaching opposing mandibular base [Figure 236]; pronotal
	lateral angle a sharply projecting right angle 17. L. eickworti, new species
	Mandibles short, just reaching opposing clypeal angle [Figure 207]; pronotal lateral angle
	obtuse, weakly projecting4

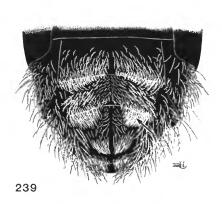

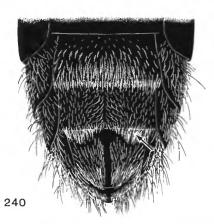

4(3). Sternum V with erect, lateral hair tufts [Figure 237]; posterior edge of sternum V with inconspicuous lateral hair lobes [Figure 237]; terga IV-VI with usual basal hair bands Sternum V without erect, lateral hair tufts [Figure 238]; posterior edge of sternum V with distinct lateral hair lobes [Figure 238]; terga IV-VI entirely covered by short, pale, 

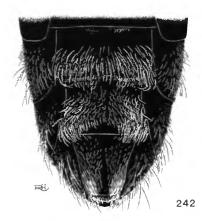

- 5(2). Pronotal lateral ridge appearing complete, not obviously interrupted by oblique lateral sulcus ([Figure 9]; minutely notched in L. transvorsum [Figure 11], where posterior margin of dorsal propodeal surface is conspicuously "V-shaped" and elevated [Figure 185]) ......6 Pronotal lateral ridge incomplete, interrupted by lateral oblique sulcus [Figure 10]....12
- 6(5). Sternum V with erect lateral hair tufts and conspicuously rounded, widely separated lateral hair lobes on posterior edge [Figure 239]; mandibles elongate, reaching midway between opposing clypeal angle and opposing mandibular base . . . . . . . . 23. L. jubatum (Vachal)

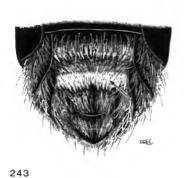

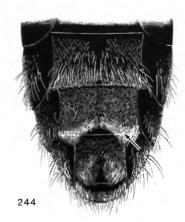

Anterior surface of tergum I lacking impunctate, hairless areas; lateral hair tufts without extremely elongate, curled hairs [Figure 242]; head moderately elongate, appearing slightly longer than broad (length/width ratio 0.91-1.0) . . . . . . . . 4. *L. asaphes*, new species

10(7).	Posterior half of dorsal propodeal surface entirely smooth, conspicuously shiny and polished
	Posterior half of dorsal propodeal surface ruguloso-striolate to striolate, not smooth and polished
11(10).	Posterior margin of dorsal propodeal surface "V-shaped" (as in [Figure 185]); head moderately elongate, appearing at least as long as broad (length/width ratio 0.96–1.04); mandibles short, just reaching opposing clypeal angle (as in [Figure 207])
	Posterior margin of dorsal propodeal surface broadly rounded; head short, appearing broader than long ([Figure 209], length/width ratio 0.77–0.92), mandibles moderately elongate, obviously reaching beyond opposing clypeal angle [Figure 209]
12(5).	Posterior half of dorsal propodeal surface entirely smooth, lacking striae and rugulae (as in
	[Figure 165]); surface of propodeum dull, obviously alveolated (as in [Figure 165]) 13
	Posterior half of dorsal propodeal surface ruguloso-striolate to striolate (as in [Figure 164]); surface of propodeum shiny, not noticeably alveolated
13(12).	Anterior half of mesoscutum with median longitudinal ridge (as in [Figure 174])
	Mesoscutum without median longitudinal ridge 1. <i>L. acarophilum</i> , new species
	and
	49. L. uyacicola (Cockerell)
14(12).	Sternum V with erect, elongate lateral hair tufts [Figure 242] 4. L. asaphes, new species
	Sternum V without erect, lateral hair tufts [Figures 243, 244]
15(14).	Posterior edge of sternum V without distinct lateral hair lobes or hair fringe; southwestern
	United States and northern Mexico [Figure 519] 28. L. morrilli (Cockerell)
16/15)	Posterior edge of sternum V with conspicuous lateral hair lobes [Figures 243, 244]16 Terga IV-V entirely covered by short, pale, adpressed pubescence (as in [Figure 1]); posterior
10(13).	edge of sternum V with conspicuous hair fringe, fringe not distinctly divided medially into lateral lobes [Figure 243]
	Terga IV-V with usual basal hair bands; posterior edge of sternum V with distinctly separated lateral hair lobes [Figure 244]
17(16).	Posterior edge of sternum V with median rosette of short, dense hairs that expand laterally into elongate hair lobes [Figure 244]

Posterior edge of sternum V without median rosette of short, dense hairs [Figures 226, 227]	
8(17). Lateral hair lobes on posterior edge of sternum V broadly rounded, moderately elongate,	18(17).
narrowly separated [Figure 226]; forewing entirely hyaline; basal half of clypeus broadly	
rounded	
Lateral hair lobes on posterior edge of sternum V narrowly rounded, elongate, widely	
separated [Figure 227]; apex of forewing infuscated; clypeus entirely flat	

## 1. Lasioglossum acarophilum, new species

FIGURES 14, 245-257

TYPE MATERIAL.—The female holotype of *L. acarophilum* is deposited in the National Museum of Natural History, Smithsonian Institution. It is missing the last two tarsomeres of the left hind leg but is otherwise in good condition. The specimen is labeled

Reef [19]04 Ar[izona]/CRBeidrman Collector/HOLO-TYPE Lasioglossum acarophilum R.J. McGinley [red label].

Seventy-eight female and 2 male paratypes are

designated and listed in the "Specimens Examined" section.

ETYMOLOGY.—The specific epithet is derived from the Greek *akari* (mite) plus *phileo* (love), a reference to the association of this species with phoretic mites.

DISTRIBUTION (Figure 245).—Lasioglossum acarophilum is presently known from southern Arizona (Cochise and Santa Cruz counties) south to Honduras. Specimens are not yet known from the northern Mexican states of Sonora, Chihuahua, and Coahuila.

DIAGNOSIS.—The combination of the elongate

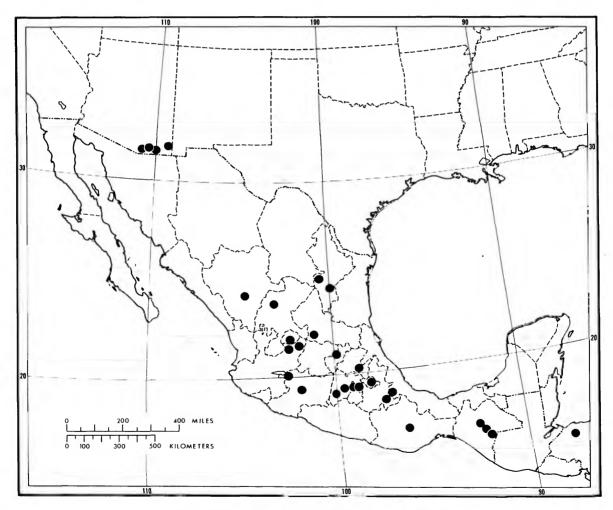

FIGURE 245.—Distribution of Lasinglossum acarophilum.

head (Figure 246), granuloso-punctate mesoscutum (Figure 251), smooth posterior half of the dorsal propodeal surface (Figure 250), and the large first tergal acarinarium (Figure 247) will distinguish *L. acarophilum* from all other known New World *Lasioglossum* except *L. uyacicola*. The latter species occurs with *L. acarophilum* in Chiapas, Mexico, but extends farther south to Panama (Figure 372). The mesoscutum of both species is actually obscurely doubly-punctate, with the smaller punctures of *L. uyacicola* (Figure 727) being much finer than those of *L. acarophilum*, giving the mesoscutum of the former species a smoother appearance under the light microscope.

In the United States only L. manitouellum has a similar granuloso-punctate mesoscutum but lacks an acarinarium. Lasioglossum desertum and L. jubatum have large tergal acarinaria but differ from L. acarophilum in having short heads (Figures 381, 473).

The smooth posterior half of the dorsal propodeal surface and the characteristic hair pattern on the posterior edge of sternum V will distinguish L. acarophilum males from other Lasioglossum except L. uyacicola. The males of these two species cannot be reliably differentiated at present. See L. uyacicola diagnosis for further details.

DESCRIPTION.—FEMALE: (1) Length 8.2–9.1 mm ( $\bar{x} = 8.7$ , n = 20); (2) wing length 2.3–3.0 mm ( $\bar{x} = 2.6$ , n = 20); (3) abdominal width 2.6–3.0 mm ( $\bar{x} = 2.8$ , n = 20).

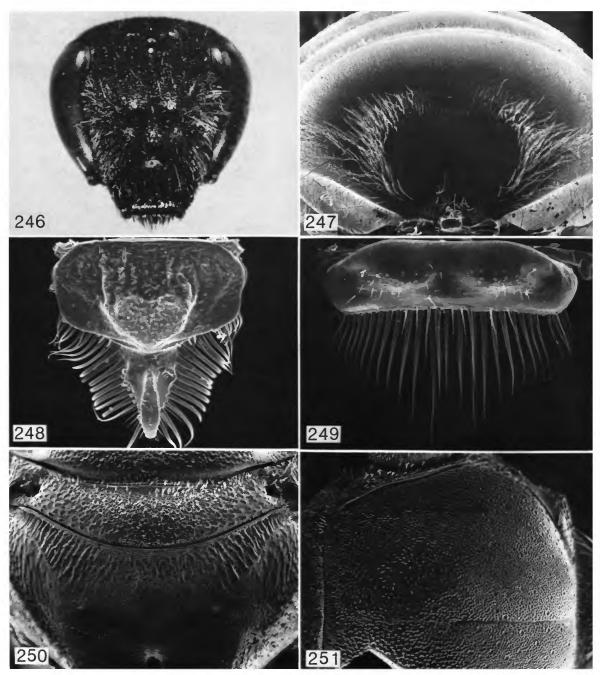

Structure: (4) Head elongate (Figure 246; length/width ratio 0.92-0.98,  $\bar{x}=0.94$ , n=34). (7) Supraclypeal area somewhat narrowly rounded, (8) protuberant. (9) Clypeus greatly projecting below lower margin of eyes, approximately 0.93 of its length below eyes; (11) surface with median longitudinal sulcation, narrow dorsally, becoming broader towards ventral edge (sometimes obscured by punctures). (14) Distance between lateral ocelli slightly exceeding distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 248; (27) distal keel moderately broad in frontal view,

lateral edges broadly bowed; (28) distal lateral projections small, triangular; (29) most fimbrial setae bluntly rounded.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) weakly elevated. (40) Dorsal surface of propodeum about 0.74 the length of scutellum and about 1.3 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle very weakly defined, median V-shaped area inconspicuous, lateral rims absent; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 14.

(46) Lateral edge of metasomal tergum II very weakly sinuate, nearly straight.

Sculpture: (47) Face dull granular, with (48) punctures of two sizes, smaller punctures dense, separated by less than their diameter, larger punctures separated by 1 to 2 times their diameter. (51) Supraclypeal area extremely granulate, (52) punctation nearly uniform, punctures separated by their width laterally, less dense centrally. (53) Clypeus granulate basally, apical half polished; (54) punctures well formed, separated by less than their width basally, less dense apically, apicolateral areas punctate. (56) Mesoscutum moderately shiny; (57) doubly-punctate (Figure 251), smaller punctures granuloso-punctate, becoming less dense posteriorly, punctures 1-2 widths apart, larger punctures separated by 2-4 times their width (observable at 50 magnifications or more). (58) Scutellum granuloso-punctate medially and along edges, less dense adjacent to median line, punctures separated by their width or slightly less. (63) Dorsal surface of propodeum incompletely striolate, striae reaching posterior margin laterally, extending only to midpoint of surface medially; (64) surface extensively alveolated. (65) Metasomal tergum 1 moderately shiny; (66) punctation fine, moderately dense, punctures slightly less than their width apart.

FIGURES 246-251.—Lasioglossum acarophilum: 246, female head; 247, female acarinarium at base of tergum I; 248, female labrum; 249, male labrum; 250, female propodeum; 251, female mesoscutum.

Coloration: (71) Wing membrane hyaline, obscurely infuscated at apex.

Vestiture: (73) Unlike most species, hairs between vertex and antennae conspicuously simple, recurved, contrasting with plumose hairs near antennae, (74) hairs white. (75) Pubescence of thorax white; (76) mesoscutal hairs sparse, inconspicuous, moderately plumose. (77) Hind tibial hair color highly differentiated, most hairs white, dorsal hairs very dark-brown to black basally, becoming light-brown to almost white distally. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II-IV white. (80) Acarinarium present (Figure 247), a large circular, glabrous area at base of tergum I, surrounded laterally and dorsolaterally by elongate fringe hairs, dorsal opening of acarinarium wide, opening subequal to width of lateral hair fringe as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 7.8-8.2 mm ( $\bar{x} = 8.0, n = 2$ ); (2) wing length 2.2-2.3 mm ( $\bar{x} = 2.2$ , n = 2); (3) abdominal width 2.0 mm ( $\bar{x} = 2.0$ , n = 2). (4) Head elongate (length/width ratio 0.91-0.96,  $\bar{x} =$ 0.94, n = 2). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (11) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 249; (23) distal process absent; (25) basal area depressed medially; (26) basal lateral depressions conspicuously developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate basally, apical half polished; (54) punctures well formed and dense basally, very fine and scattered over apical half. (68) Clypeal maculation present. (69) Flagellum yellowish orange ventrally. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 252; (82) hairs on sternum IV elongate, suberect; (83) sternum V without conspicuous erect hairs, posterior edge with straight-edged adpressed lateral hair lobes.

Terminalia: Sterna VII-VIII as in Figure 256; (85) sternum VIII with acute median process. Genitalia as in Figures 253–255; (86) gonobase elongate; (87) gonostylus extremely elon-

FIGURE 252.—Lasioglossum acarophilum, male sternal vestiture.

gate and slender; (88) retrorse membranous lobe present, (89) slender, sharply pointed; (90) volsella with moderately prominent lateral lobe.

FLIGHT RECORDS (Figure 257).—Lasioglossum acarophilum females have been collected from late March through December. Most records are from July and August, with a peak in early August. One male was collected in December.

FLOWER RECORDS.—Females (12): Labiatae 33%; Compositae 25%; Convolvulaceae 17%; Leguminosae 17%. Total: 6 families, 9 genera as follows:

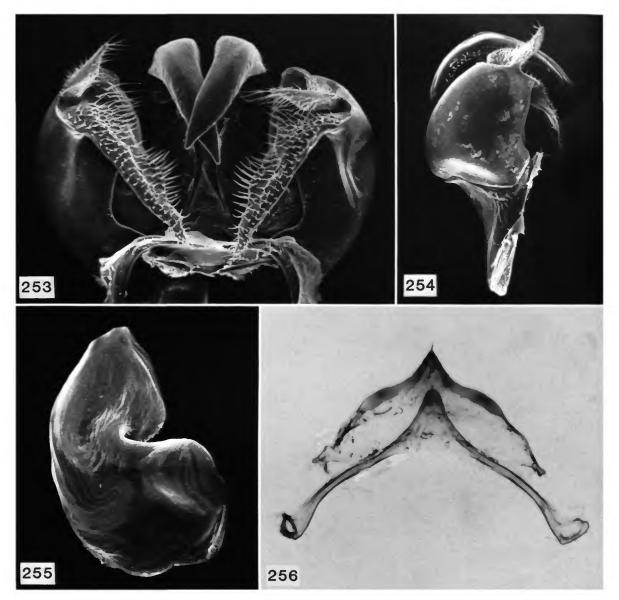

Helenium 19; \*Helianthus 1(1)9; Heterotheca 19; Ipomoea 29; Leucophyllum 19; Monarda 19; Prosopis 19; Salvia 39; \*Solanum 19.

Specimens Examined.—79 (77 $\mathbb{2}$ , 2 $\delta$ ).

### 2. Lasioglossum aequatum (Vachal)

FIGURES 16, 258-260

Halictus aequatus Vachal, 1904:473 [female].—Cockerell, 1905a:90 [key].

Lasioglossum aequatum.—Moure and Hurd, 1986:59 [catalog].

TYPE MATERIAL.—The female holotype is in the Naturhistorisches Museum, Vienna. At some time, the head and front legs were broken off and crudely glued back to the thorax, the vertex being attached to the pronotum and mesoscutum. The left front leg is missing and the metasomal basal hair bands are matted and dark. The specimen is labeled

Forrer./Mexico Mazatl[an] 1883. 111 [March] Farrer./aequatus Vach.[al] det. J. Vachal/Hal.[ictus] aequatus Vach.[al] [handwritten]/LASIOGLOSSUM 

Lasioglossum aequatum (Vachal, 1904) Holotypus des. A.W. Ebmer 1980 [right edge with red border].

DISTRIBUTION (Figure 258).—Only three female specimens of this Mexican species are known: the holotype from Mazatlan, one specimen from near Mexico City, and another from El Chico, Hidalgo.

DIAGNOSIS.—Lasioglossum aequatum is unique in having the dorsal propodeal surface strongly and regularly striate, the striae being fine and reaching the posterior propodeal margin (Figure 259). Other helpful characters are as follows: head short (similar to Figure 303); mesoscutum coarsely granuloso-punctate (similar to Figure 336 but punctures not so large); acarinarium absent; forewing membrane hyaline with infuscated apex. Lasioglossum costale is similar but in addition to differing in propodeal sculpture has pale orange wing membranes and less coarse mesocutal punctation. Lasioglossum crocoturum and L. cercothrix have metasomal terga IV-V entirely covered by short, adpressed pubescence (Figure 1). Lasioglossum tricnicos is superficially similar but has the anterior costal edge of the forewing conspicuously infuscated.

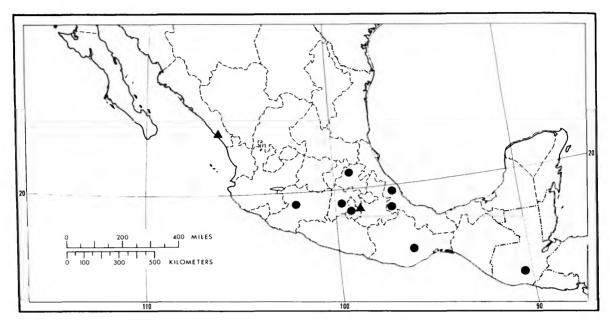

FIGURE 258.—Distribution of Lasioglossum aequatum (triangle) and L. circinatum (circle).

DESCRIPTION.—FEMALE: (1) Length 7.9–8.9 mm ( $\bar{x} = 8.3$ , n = 3); (2) wing length 2.2–2.4 mm ( $\bar{x} = 2.3$ , n = 3); (3) abdominal width 2.5–2.6 mm ( $\bar{x} = 2.5$ ).

Structure: (4) Head short (similar to Figure 303; length/width ratio 0.83-0.92,  $\bar{x}=0.88$ , n=3). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.78 of its length below lower margin of eyes; (11) surface with weakly developed median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellis and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. (27) Labral distal keel broad in frontal view, spoonshaped with conspicuous basal, median groove; (28) distal lateral projections absent; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse, sharply pointed; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal

surface of propodeum about 0.74 the length of scutellum and about 1.3 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin very broadly rounded; (43) propodeal triangle weakly defined, median V-shaped elevation inconspicuous; (44) lateral carinae extending to dorsal surface, becoming weakly defined along dorsal edge. (45) Tibial spur as in Figure 16.

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) punctation sparse and scattered. (53) Clypeus granulate throughout; (54) punctures separated by their width or less basally, slightly less dense apically. (56) Mesoscutum moderately shiny; (57) punctures coarse, contiguous to nearly contiguous throughout, interspaces granulate, becoming obscurely scabrous anteriorly. (58) Scutellum densely punctate throughout, punctures adjacent to median line coarse, similar to those of mesoscutum. (63) Dor-

FIGURES 259, 260.—Lasioglossum aequatum, female: 259, propodeum; 260, labrum.

sal surface of propodeum (Figure 259) strongly and regularly striate, striae reaching posterior margin; (64) surface not noticeably alveolated. (65) Metasomal tergum I moderately shiny; (66) surface granuloso-punctate.

Coloration: (71) Wing membrane mostly hyaline, marginal cell and apex infuscated.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax pale yellowish brown; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, most hairs white, dorsal hairs light to dark brown. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

## 3. Lasioglossum argutum, new species

FIGURES 18, 261-273

TYPE MATERIAL.—The female holotype is in the Snow Museum, University of Kansas, Lawrence. It is labeled

7 mi SE Nochixtlan Oaxaca Mexico VII [Jul] 5 1953 6700 ft/Univ. Kans.[as] Mex.[ican] Expedition/Nolina Taken on/HOLOTYPE Lasioglossum argutum R.J. McGinley [red label].

One hundred fifteen female paratypes and 33 male paratypes are designated and listed in the "Specimens Examined" section below.

ETYMOLOGY.—The specific epithet is derived from the Greek *argutus* (clear or bright), a reference to the conspicuously shiny dorsal propodeal surface characteristic of this species.

DISTRIBUTION (Figure 261).—Lasioglossum argutum is presently known from south-central Mexico from San Luis Potosi south to Oaxaca.

DIAGNOSIS.—Both sexes of *L. argutum* can be recognized by the smooth, highly polished posterior one-third to one-half of the dorsal propodeal surface (Figure 266). *Lasioglossum bajaense* has a similar propodeum but is known only from Baja California, has a large metasomal acarinarium (absent in *L. argutum*), and has relatively sparse mesoscutal punctation (the mesoscutum of *L. argutum* is obscurely doubly-punctate with the smaller punctures nearly contiguous, Figure 267). Other characters helpful in recognizing both sexes of *L. argutum* are the short head (Figures 262, 263) and the complete pronotal lateral carina (see Figure 9).

DESCRIPTION.—FEMALE: (1) Length 7.1–8.6 mm ( $\bar{x} = 8.0$ , n = 15); (2) wing length 2.2–2.5 mm ( $\bar{x} = 2.4$ , n = 15); (3) abdominal width 2.4–2.7 mm ( $\bar{x} = 2.5$ , n = 15).

Structure: (4) Head short (Figure 262; length/width ratio 0.84-1.0,  $\bar{x} = 0.89$ , n = 15).

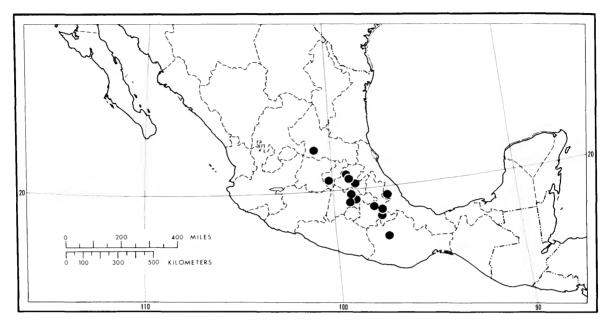

FIGURE 261.—Distribution of Lasioglossum argutum.

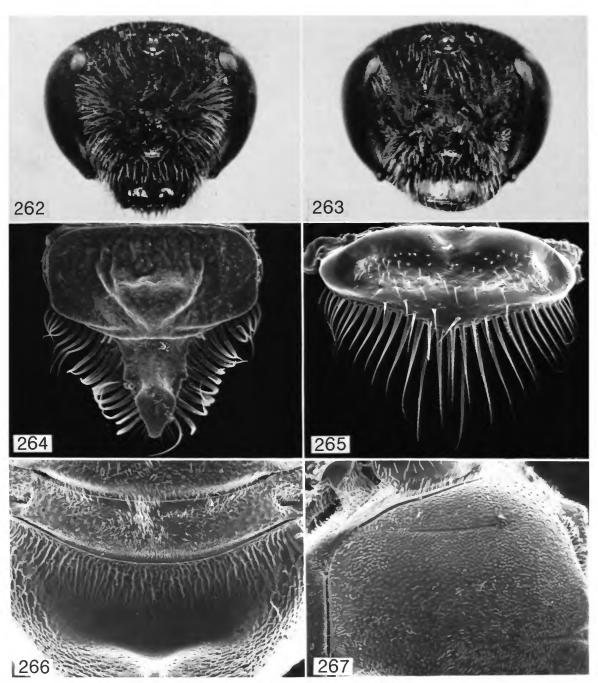

(7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.73 of its length below lower margin of eyes; (11) surface with distinct median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 264; (27) distal keel extremely broad in frontal view, widest basally; (28) distal lateral projections small, narrowly rounded; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle forming right angle; (33) pronotal lateral ridge appearing complete, indistinctly notched by obscure oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.86 the length of scutellum and about 1.5 times the length of metanotum, (41) very slightly depressed centrally, (42) posterior margin rounded; (43) propodeal triangle very weakly defined, evident medially as a very low, inconspicuous V-shaped ele-

vation without lateral rims; (44) lateral carinae extending to about midpoint of posterior surface. (45) Tibial spur as in Figure 18.

(46) Lateral edge of metasomal tergum II broadly and shallowly concave.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) punctation very sparse with few, scattered punctures. (53) Clypeus granulate basally, apical two-thirds polished; (54) punctures very sparse, obscure, apicolateral areas virtually impunctate. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 267, obscurely doubly-punctate, smaller punctures dense, contiguous or nearly contiguous throughout, larger punctures obscure, separated by 3-4 times their width. (58) Scutellum doubly punctate throughout, smaller punctures separated by their width or slightly less, larger punctures scattered. (63) Dorsal surface of propodeum (Figure 266) striolate laterally and over basal two-thirds medially, posterior third smooth and conspicuously polished; (63) posterior half smooth, not

FIGURES 262-267.—Lasioglossum argutum: 262, female head; 263, male head; 264, female labrum; 265, male labrum; 266, female propodeum; 267, female mesoscutum.

alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white on gena and near antennae, becoming pale yellowish brown on vertex. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color weakly differentiated, most hairs white to pale yellowish brown, dorsal hairs brown basally. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 6.4–8.7 mm ( $\bar{x} = 7.5$ , n = 10); (2) wing length 1.9–2.3 mm ( $\bar{x} = 2.1$ , n = 10); (3) abdominal width 1.7-2.0 ( $\bar{x} = 1.9$ , n = 10). (4) Head as in Figure 263 (length/width ratio 0.82-0.96, x = 0.89, n = 10). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (11) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 265; (24) distal process weakly developed, rounded; (25) basal area depressed medially; (26) basal lateral depressions conspicuously developed. (30) Mandible moderately elongate, reaching slightly beyond opposing clypeal angle. (53) Clypeus mostly polished, granulate along basal edge; (54) punctures well formed, nearly contiguous along basal edge, apical two-thirds virtually impunctate with very fine widely scattered punctures. (68) Clypeal maculation present (Figure 263). (69) Flagellum entirely dark or slightly paler ventrally than on dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 268; (82) hairs on sternum IV moderately elongate, suberect, with conspicuous band of hairs near posterior edge of sternum; (83) sternum V with median rosette of short hairs, posterior sternal edge with conspicuous, broadly rounded lateral hair lobes that are only weakly separated medially.

Terminalia: Sterna VII-VIII as in Figure 272; (85) sternum VIII with extremely elongate,

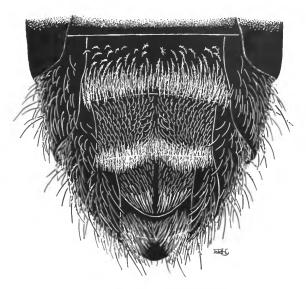

FIGURE 268.—Lasioglossum argutum, male sternal vestiture.

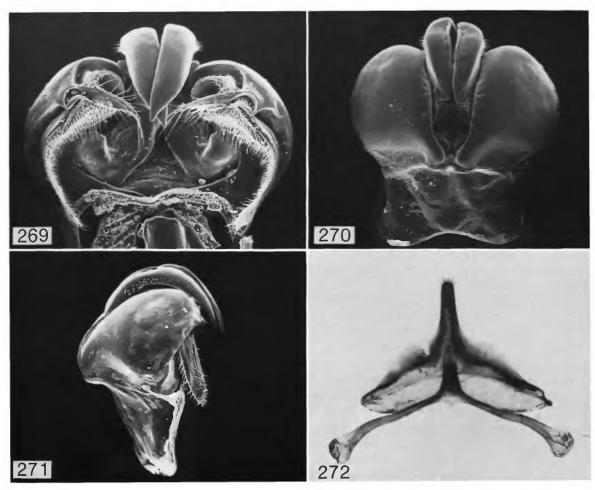

slender median process. Genitalia as in Figures 269–271; (86) gonobase moderately elongate; (87) gonostylus elongate, slender; (88) retrorse membranous lobe present, (89) slender, somewhat narrowly rounded apically; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS (Figure 273).—Females have been collected in most months from February through October, with most records from late February, late June, and early July. Most male records are from June but the range is from February and June through October.

FLOWER RECORDS.—Females (25): Liliaceae 44%; Anacardiaceae 32%; Compositae 12%. Males (4): Malvaceae 50%; Anacardiaceae 25%; Compositae 25%. Total: 29 in 6 families, 8 genera as follows:

Baccharis 1\(\text{?}\); Eupatorium 2\(\text{?}\); Flourensia 1\(\delta\); \*Gaura 1(1)\(\text{?}\); Malva 1\(\text{?}\), \(\delta\); \*Nolina 11(11)\(\text{?}\); \*Opuntia 1(1)\(\text{?}\); \*Schinus 8\(\text{?}\), 1\(\delta\).

MITE ASSOCIATES.—Lasioglossum argutum females do not have an acarinarium on the first metasomal tergum; however, five (4.4%) of the 114 females examined had hypopodes on this surface. None of the 31 males examined carried mites.

FIGURES 269-272.—Lasioglossum argutum, male: 269, genitalia, ventral view; 270, same, dorsal view; 271, same, lateral view; 272, sterna VII-VII.

# 4. Lasioglossum asaphes, new species

FIGURES 19, 242, 274-280, 282-286

Type Material.—The female holotype of Lasioglossum asaphes is deposited in the National Museum of Natural History, Smithsonian Institution. The specimen is labeled

MEXICO, Chis. [Chiapas] SanCristobal [de] las Casas, VII [July]-17-21-[19]64 Paul J. Spangler/HOLOTYPE Lasioglossum asaphes R.J. McGinley [red label].

The holotype is missing the mid left tibia and tarsus but otherwise is in good condition. Sixty female and six male paratypes are listed in the "Specimens Examined" section.

ETYMOLOGY.—The specific epithet is taken from the Greek asaphes (obscure, baffling), alluding to the difficulty in distinguishing this somewhat generalized species.

DISTRIBUTION (Figure 274).—Lasioglossum asaphes is presently known from 61 females and

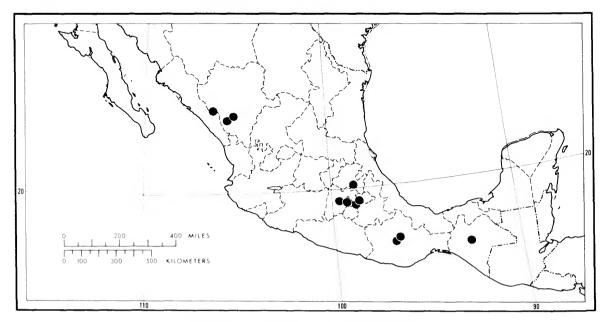

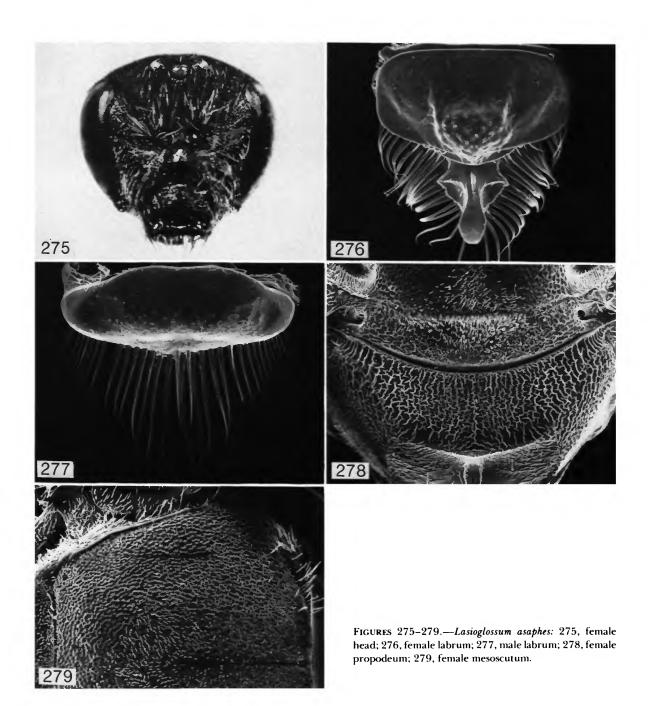

FIGURE 274.—Distribution of Lasinglossum asaphes.

six males. It occurs in Mexico from Sinaloa and Durango south to Chiapas.

DIAGNOSIS.—The combination of the entirely granuloso-punctate mesoscutum (Figure 279;

not contiguously coarse as in *L. cercothrix* (Figure 313) and *L. aequatum*), the ruguloso-striolate dorsal propodeal surface (Figure 278), the absence of a metasomal acarinarium and lack of

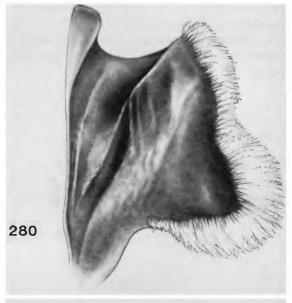

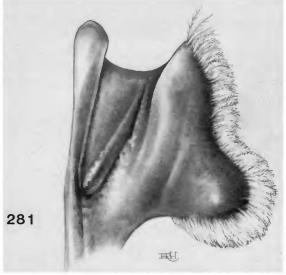

conspicuous infuscation along the anterior edge of the forewing (as in L. crocoturum, L. tricnicos and L. eickworti, Figure 235) will distinguish the females of L. transvorsum, L. asaphes, L. xyriotropis, L. costale, and L. manitouellum from other New World Lasioglossum. Lasioglossum transvorsum differs from the above species in having an elongated, V-shaped posterior propodeal margin (Figure 650) and characteristic adpressed hair patches on the anterior surface of tergum I. Lasioglossum asaphes and L. xyriotropis differ from the latter three species in having a complete pronotal lateral carina (not distinctly interrupted as in Figure 281). The pronotal carina of L. xyriotropis is obviously complete (Figure 732), whereas that of L. asaphes appears to be almost interrupted by a deep, oblique, lateral sulcus (Figure 280). Furthermore, the head of L. xyriotropis is shorter than that of L. asaphes and the clypeus of the former species is strongly granulate throughout (apical half shiny in L. asaphes).

Males of L. asaphes are similar to the females in pronotal structure and propodeal sculpture. They have erect hair tufts on the lateral edges of sternum V (Figure 242). Among Mexican species, similar hair tufts are found elsewhere in males of L. tricnicos and L. pallicorne. Lasioglossum tricnicos males have the anterior edge of the forewing conspicuously infuscated (hyaline in L. asaphes), and the sternal hair tufts of L. pallicorne males include some hairs that are conspicuously elongate and curled (Figure 576). Males of L. xyriotropis are not known.

DESCRIPTION.—FEMALE: (1) Length 8.2–9.5 mm ( $\bar{x} = 9.0$ , n = 15); (2) wing length 2.6–2.9 mm ( $\bar{x} = 2.7$ , n = 15); (3) abdominal width 2.6–3.0 mm ( $\bar{x} = 2.8$ , n = 15).

Structure: (4) Head elongate (Figure 275; length/width ratio 0.85-1.0,  $\bar{x}=0.96$ , n=15). (7) Supracylpeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.87 of its length below lower margin of eyes; (11) surface with obscure median longitudinal sulcation. (14) Distance between lateral ocelli slightly exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum

FIGURES 280, 281.—Female pronota: 280, L. asaphes; 281, L. costale.

as in Figure 276; (27) distal keel very broad in frontal view, spoon-shaped, with conspicuous basal median groove; (28) distal lateral projections extremely well developed, sharply projecting (as in *L. bajaense*); (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse;

(33) pronotal lateral ridge appearing complete, obscurely notched by narrow oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged near oblique sulcus, becoming narrowly rounded ventrally. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.88 the length of scutellum and about 1.7 times the length of metanotum, (41) depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle very weakly defined laterally, evident medially as an inconspicuous V-shaped elevation with sharp-edged lateral rims, fading towards metanotum; (44) lateral carinae extending beyond midpoint of posterior surface, obscurely reaching dorsal surface. (45) Tibial spur as in Figure 19.

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face moderately shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area moderately granulate with small polished central area; (52) punctures separated by 1-2 times their width laterally, impunctate centrally. (53) Clypeus granulate basally, apical half polished; (54) punctures obscure basally, separated by less than their width, larger and less dense on apical half. (56). Mesoscutum moderately shiny; (57) punctation as in Figure 279, punctures extremely dense and contiguous throughout, becoming granuloso-punctate anteriorly. (58) Scutellum densely punctate to granuloso-punctate with small but conspicuous impunctate areas adjacent to median line. (63) Dorsal surface of propodeum (Figure 278) very strongly ruguloso-striolate laterally, becoming rugulose medially, striae and rugulae reaching posterior margin; (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration. (71) Wing membrane mostly hyaline, apex lightly infuscated.

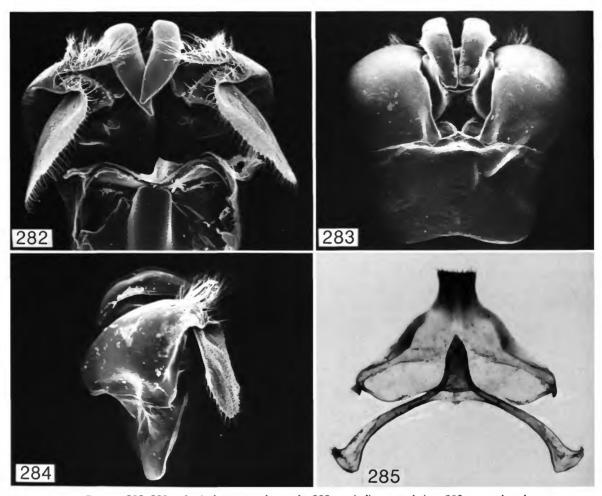

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax mostly pale yellowish brown, more brownish on meso-

scutum and scutellum; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, ventral and lateral hairs white, dorsal hairs brown to dark brown. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum 1.

MALE: Similar to female except as follows: (1) length 7.3-9.0 mm ( $\bar{x} = 8.0$ , n = 7); (2) wing length 2.2-2.5 mm ( $\bar{x} = 2.3$ , n = 7); (3) abdominal width 1.9-2.2 mm ( $\bar{x} = 2.1$ , n = 7). (4) Head elongate (length/width ratio 0.91-1.0,  $\bar{x} = 0.98$ , n = 7). (5) Gena slightly wider than eye, (6) moderately produced posteriorly. (11) Clypeal surface shallowly depressed ventrally. (23) Unlike most species, flagellomere 1 relatively long compared to flagellomere 2 (ratio 1:2 approximately 0.90). Labrum as in Figure 277; (24) distal process very weakly developed, rounded; (25) basal area depressed medially; (26) basal lateral depressions conspicuously developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate basally, apical two-thirds polished; (54) punctures well-formed, nearly contiguous basally, apical two-thirds with large and small, widely scattered punctures. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 242; (82) hairs on sternum IV suberect, moderately elongate, becoming elongate laterally; (83) sternum V with median rosette of short hairs that abruptly become elongate and erect laterally, posterior edge of sternum with widely spaced lateral hair lobes.

Terminalia: Sterna VII-VIII as in Figure 285; (85) sternum VIII with truncated, semicircular median process. Genitalia as in Figures 282–284; (86) gonobase moderately elongate; (87) gonostylus elongate, moderately broad, apex broadly rounded; (88) retrorse membranous lobe present (89) moderately broad (unlike other species except *L. tranvorsum*, apex of gonocoxite near base of retrorse lobe with moderately long, medially directed membranous flap); (90) volsella with prominent lateral lobe.

FIGURES 282-285.—Lasioglossum asaphes, male: 282, genitalia, ventral view; 283, same, dorsal view; 284, same, lateral view; 285, sterna VII-VIII.

FLIGHT RECORDS (Figure 286).—Females of *L. asaphes* have been collected from late March to early November, with most records from late July (the November records are from Oaxaca). Males have been collected in July and August.

FLOWER RECORDS.—One pollen-laden female taken from *Penstemon gentianoides* in Oaxaca, Mexico.

Specimens Examined.—67 (619, 68).

#### 5. Lasioglossum athabascense (Sandhouse)

FIGURES 20, 287-299

Halictus athabascensis Sandhouse, 1933:78 [male, female].—
 Brittain and Newton, 1934:262 [flower records].
 Lasioglossum athabascense.—Michener, 1951:1106 [Nearctic catalog].—Mitchell, 1960:340 [key, redescription, locality data, flower records].—Knerer and Atwood, 1962:162

[locality data, flower records, Ontario].—Hurd, 1979:

1957 [Nearctic catalog].—Hansen and Osgood, 1983:150 [flower records: *Rubus*].

TYPE MATERIAL.—The male holotype is labeled

70 mi. up Athabasca R[iver] Alta (Alberta]/Mer[ritt] Cary Collector/Type No. 44882 U.S.N.M. [red label]/Halictus athabascensis Sandhouse Type [handwritten].

The holotype is in excellent condition and is in the National Museum of Natural History, Smithsonian Institution. Sandhouse designated an allotype and 38 paratypes (15 females, 23 males). The paratypes are in the collections of the National Museum of Natural History (NMNH; including allotype), University of California, Riverside, and the Canadian National Collection. One female paratype from Kaslow, British Columbia, was misassociated in the original series and is actually a specimen of *L. egregium* (Vachal).

DISTRIBUTION (Figure 287).—This transcontinental species, which ranges from Nova Scotia and Prince Edward Island to the Pacific Coast, has the most northern known distribution of New World Lasioglossum. In the West it ranges from Fort Simpson, Northwest Territories (61°46' north latitude) south through the Cascade Range to Oregon and through the Rocky Mountains to Colorado and Utah. The most southern known eastern localities are in southern Pennsylvania. Hurd (1979), based on Mitchell (1960), reported L. athabascense from Ohio and south to North Carolina. Mitchell's records from Virginia and North Carolina are most likely based on misidentifications of L. coriaceum and L. forbesii, sensu lato.

DIAGNOSIS.—Females of this nondescript species are best characterized by the following character combination: acarinarium absent (elongate hairs scattered over anterior surface of metasomal tergum I); dorsal surface of propodeum irregularly striolate to rugulose (Figure 292); head moderately short (Figure 288, length/width ratio 0.92-0.97,  $\bar{x}=0.95$ , n=14, Fort Simpson, N.W.T.; 0.94-0.98,  $\hat{x}=0.96$ , n=20, Ithaca, N.Y.).

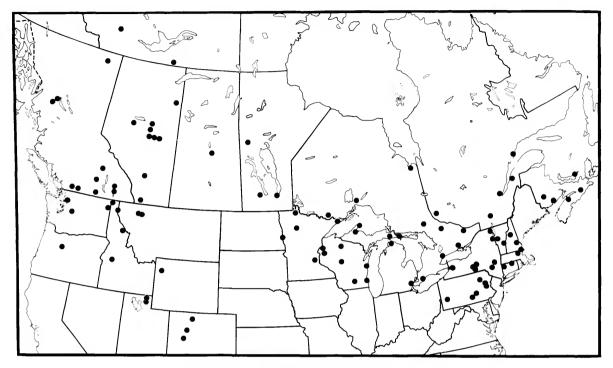

FIGURE 287.—Distribution of Lasinglossum athabascense.

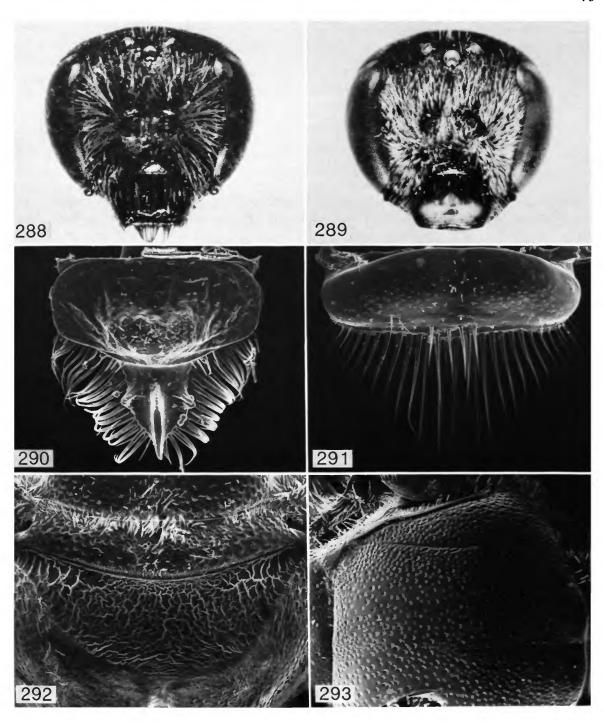

In the central and eastern portions of its range, L. athabascense females are commonly confused with those of L. coriaceum and L. forbesii (sensu lato). The presence of an acarinarium in the latter two species (Figures 72, 407-409) easily separates them from L. athabascense. Another common eastern species, L. fuscipenne, also lacks an acarinarium but can be immediately identified by its distinctive propodeum that is truncated posteriorly and uniquely sculptured (Figure 448). In the West the diagnostic character combination will separate L. athabascense from other Lasioglossum except for L. manitouellum, L. lampronotum, L. colatum, and L. anhypops. L. manitouellum is easily differentiated by its granulosopunctate mesoscutum (Figure 510). The conspicuously wide head of L. lampronotum (Figure 486), the deeply excavated lateral margin of metasomal tergum II of L. anhypops (Figure 154), and the short, adpressed hair patches on metasomal tergum I of L. colatum (Figure 84) will readily distinguish these species from L. athabascense.

Lasioglossum athabascense males can be recognized by the distinctive hair pattern on sternum V (Figure 294): from the median line, short hairs gradually and evenly increase in length to form elongate lateral hair tufts. Other Lasioglossum males in the United States having similar hair tufts are L. egregium and L. mellipes, which differ from L. athabascense by having elongate heads (Figures 684, 698; the head of L. athabascense is short and rounded, Figure 289). In eastern United States L. athabascense males are often confused with L. forbesii and L. paraforbesii, but the yellow tarsi of the latter two species versus the dark tarsi of L. athabascense will easily differentiate these forms.

DESCRIPTION.—FEMALE: (1) Length 8.6–10.7 mm ( $\bar{x} = 9.6$ , n = 20); (2) wing length 2.6–3.1 mm ( $\bar{x} = 2.8$ , n = 20); (3) abdominal width 2.7–3.3 mm ( $\bar{x} = 3.0$ , x = 20).

Structure: (4) Head moderately short (Figure 288; length/width ratio 0.88-1.0,  $\bar{x}=0.94$ , n=34). (7) Supraclypeal area evenly rounded, (8)

NUMBER 429

FIGURES 288–293.—Lasioglossum athabascense: 288, female head; 289, male head; 290, female labrum; 291, male labrum; 292, female propodeum; 293, female mesoscutum.

moderately protuberant. (9) Clypeus projecting approximately 0.74 its length below lower margin of eyes, (11) median longitudinal sulcation weakly developed to absent. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 290; (27) distal keel narrow, parallel-sided in frontal view; (28) distal lateral projections well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated. (40) Dorsal surface of propodeum about 0.88 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, median V-shaped portion inconspicuous to weakly elevated, lateral rims absent; (44) lateral carinae extending to midpoint of posterior surface or only slightly beyond. (45) Tibial spur as in Figure 20.

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area usually moderately granulate (polished towards center in some specimens), (52) punctation nearly uniform, punctures 1-2 times their width apart laterally, becoming sparsely punctate centrally. (53) Clypeus granulate basally and most of median area to apex, polished laterally; (54) punctures well formed basally, separated by less than their width, becoming larger, obscure and less dense apically, apicolateral areas largely impunctate. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 293, punctures separated by their width or less laterally and anteriorly (often contiguously punctate along anterior edge), becoming more sparsely punctate centrally, punctures separated by 1-4 times their width. (58) Scutellar punctation nearly uniform, punctures finer and less dense than those of central area of mesoscutum. (63) Dorsal surface of propodeum variable in sculpture, irregularly striolate to rugulose (Figure 292); (64) surface smooth, not alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, moderately dense, punctures 1– 1.5 times their width apart.

Coloration: (71) Wing membrane very light yellowish brown.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax mostly pale yellowish brown, white on pronotal lateral angle, pronotal lobe and metanotum; (76) mesoscutal hairs moderately sparse and plumose. (77) Hind tibial hairs concolorous, yellowish brown. (78) Anterior hairs of metasomal tergum I white to pale yellowish brown, (79) basal hair bands of terga II–IV white to yellowish white; (80) acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 7.4–9.2 mm ( $\bar{x} = 8.1$ , n = 20); (2) wing

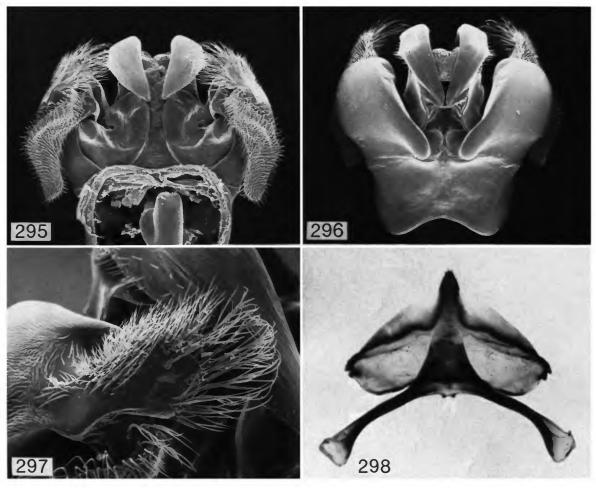

FIGURE 294.—Lasioglossum athabascense male sternal vesti-

length 2.1-2.7 mm ( $\bar{x}=2.4$ , n=20); (3) abdominal width 2.0-2.5 mm ( $\bar{x}=2.2$ , n=20). (4) Head as in Figure 289 (length/width ratio 0.91-1.0,  $\bar{x}=0.95$ , n=20). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (11) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 291; (24) distal process absent; (25) basal area depressed medially; (26) basal lateral depressions very weakly developed, inconspicuous, nearly flat areas. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed along basal edge, becoming very fine and

scattered over apical two-thirds. (68) Clypeal maculation present (Figure 289). Flagellum pale yellowish orange ventrally, contrasting strongly with dark dorsal surface. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 294; (82) hairs on sternum IV dense, elongate, erect; (83) sternum V with median rosette of moderately short, erect hairs that gradually become longer laterally to form erect lateral hair tufts.

Terminalia: Sterna VII-VIII as in Figure 298; (84) unlike most species, median process of sternum VII relatively broad; (85) sternum VIII

FIGURES 295-298.—Lasioglossum athabascense, male: 295, genitalia, ventral view; 296, same, dorsal view; 297, gonostylus; 298, sterna VII-VIII.

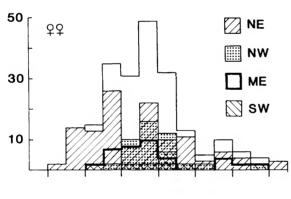

with short, narrowly rounded median process. Genitalia as in Figures 295–297; (86) gonobase moderately elongate; (87) gonostylus extremely broad, apex broadly triangular; (88) retrorse membranous lobe present, (89) moderately broad, tapering apically; (90) volsella with very prominent lateral lobe.

FLIGHT RECORDS (Figure 299).—Females of *L. athabascense* have been collected from April through early October, with most records from late April through July. Most males have been collected in late August, with records extending from July to October.

FLOWER RECORDS.—Females (58): Rosaceae 47%; Cruciferae 16%; Compositae 12%; Salicaceae 12%. Males (3): Compositae 67%; Balsaminaceae 33%. Total: 61 in 11 families, 18 genera as follows:

Aster 16: Barbarea 79; \*Brassica 2(1)9; Chrysothamnus 19; Eupatorium 16; Hackelia 19; Impatiens 16; Inula 29; Melilotus 29; Penstemon 29; Pyrus 19; \*Rubus 25(18)9; Salix 79; Spiraea 19; Tamarix 19; Taraxacum 49; Vaccinium 19; Viola 19.

SPECIMENS EXAMINED.—361 (2792, 828).

### 6. Lasioglossum bajaense, new species

FIGURES 21, 300-301

TYPE MATERIAL.—The female holotype is labeled

MEX.[ico], B.[aja] C.[alifornia] Sur:trail, LaBurrera-La-Laguna, Sierra de LaLaguna, 850 m.[eters] 28-VIII [August]-'[19]77 coll.[ector] R.R. Snelling/HOLOTYPE Lasioglossum bajaense R.J. McGinley [red label].

The holotype is in excellent condition except for missing the fifth tarsomere of the right hind leg. It is deposited in the Los Angeles County Museum of Natural History, Los Angeles, California.

Two female paratypes, also from La Laguna, Baja California, are in the California State Collection of Arthropods, Sacramento, California,

and in the collection of the National Museum of Natural History, Smithsonian Institution.

DISTRIBUTION (Figure 300).—Lasioglossum bajaense is presently known from only three females collected from La Laguna, Baja California, in 1977 and 1979.

DIAGNOSIS.—The smooth, highly polished posterior half of the dorsal propodeal surface will distinguish L. bajaense from all other New World Lasioglossum except L. argutum (smooth propodeal surfaces in other species are dull, not shiny). Along with differences in distribution (Figures 261, 300) these two species can be differentiated by the presence of a large metasomal acarinarium in L. bajaense (similar to that of L. uyacicola, Figure 728). Lasioglossum argutum lacks an acarinarium and is a much smaller bee (length 7.1-8.6,  $\bar{x}=8.0$  vs. 8.2-9.2,  $\bar{x}=8.8$ ).

DESCRIPTION.—FEMALE: (1) Length 8.2-9.2 mm ( $\bar{x} = 8.8$ , n = 3); (2) wing length 2.5-2.8 mm ( $\bar{x} = 2.7$ , n = 3); (3) abdominal width 2.5-2.8 mm ( $\bar{x} = 2.7$ , n = 3).

Structure: (4) Head moderately short (ap-

pearing slightly shorter than that of L. athabascence, Figure 288; length/width ratio 0.88-0.92,  $\bar{x} = 0.91$ , n = 3). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.71 of its length below lower margin of eyes; (11) median longitudinal sulcation apparently absent, possibly obscured by punctation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 301; (27) distal keel broad in frontal view, spoon-shaped with conspicuous basal median groove; (28) distal lateral projections extremely well developed, sharply projecting as in L. asaphes; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle moderately obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.82 the length of

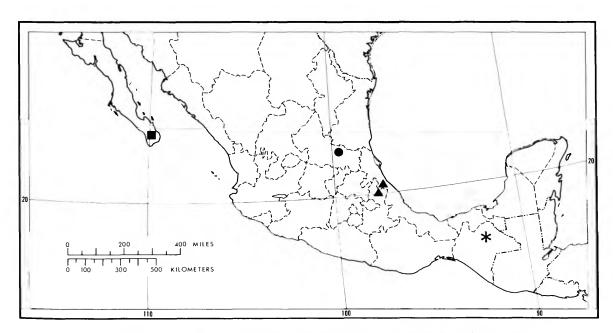

FIGURE 300.—Distribution of Lasinglossum bajaense (square), L. orphnaeum (triangle), L. perscabrum (circle), and L. tropidonotum (asterisk).

FIGURE 301.—Lasioglossum bajaense, female labrum.

scutellum and about 1.5 times the length of metanotum, (41) very slightly depressed centrally, (42) posterior margin rounded; (43) propodeal triangle weakly defined, evident medially as a low V-shaped elevation and lateral impressed lines (elevated lateral rims absent); (44) lateral carinae extending just beyond midpoint of posterior surface. (45) Tibial spur as in Figure 21.

(46) Lateral edge of metasomal tergum II only faintly sinuate, virtually straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area obscurely granulate, very shiny; (52) punctures separated by their width laterally, becoming sparse centrally. (53) Clypeus polished; (54) punctures separated by less than their width basally and medially, apicolateral areas largely impunctate. (56) Mesoscutum moderately shiny; (57) doubly-punctate, smaller punctures separated by 1-2 times their width, larger punctures 2-4 times their width apart. (58) Scutellar punctation weakly developed, obscurely doubly-punctate; smaller punctures extremely fine, inconspicuous, separated by 1-5 times their width, larger punctures widely scattered. (63) Dorsal surface of propodeum ruguloso-striolate over basal half, posterior half smooth, somewhat polished; (64) basal half alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures less than their width apart.

Coloration: (71) Wing membrane mostly hyaline, apex lightly infuscated.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color weakly differentiated, most hairs white, dorsal hairs brown to light brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium present (similar to Figure 728), a large, circular, glabrous area surrounded laterally and dorsolaterally by elongate fringe hairs; dorsal opening of acarinarium wide, wider than width of lateral fringe hairs as seen in dorsal view.

SPECIMENS EXAMINED.—39.

# 7. Lasioglossum bardum (Cresson)

FIGURES 22, 302-308

Halictus bardus Cresson, 1872:251 [female].—Dalla Torre, 1896:55 [World catalog].—Cockerell, 1897:163, 165 [locality and flower records, taxonomic notes]; 1898a:46 [key]; 1898c:51 [taxonomic notes]; 1906:294 [locality record]; 1916a:254 [taxonomic notes].—Cresson, 1916:107 [lectotype designation].

Lasioglossum bardum.—Michener, 1951:1106 [Nearctic catalog].—Hurd, 1979:1957 [Nearctic catalog].

Lasioglossum bardus.—Moldenke and Neff, 1974:52 [distribution and floral records; incorrectly reported from Arizona, California, and New Mexico].

TYPE MATERIAL.—Cresson's original description of *Halictus bardus* was based on two female syntypes from the Belfrage collection. Cresson later (1916) designated one of the specimens as the lectotype. This specimen is in the Academy of Natural Sciences at Philadelphia and is labeled

Tex.[as]/TYPE No. 2116 [red label]/Halictus bardus 665

Cr[esson][handwritten]/LECTOTYPE Halictus bardus Cresson des.[ignated by] Cresson, 1916 [handwritten, red label, labeled by McGinley, 1983].

The lectotype is an excellent condition except for missing the last two tarsomeres on both hind legs. The paralectotype is in the National Museum of Natural History, Smithsonian Institution

DISTRIBUTION (Figure 302).—Lasioglossum bardum is presently known from 111 female specimens collected from seven counties in central Texas. Hurd (1979) indicated that this species is found from Texas to California; however, the

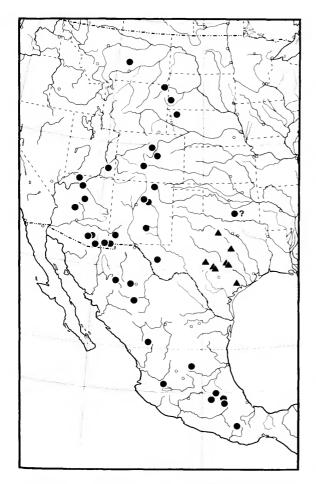

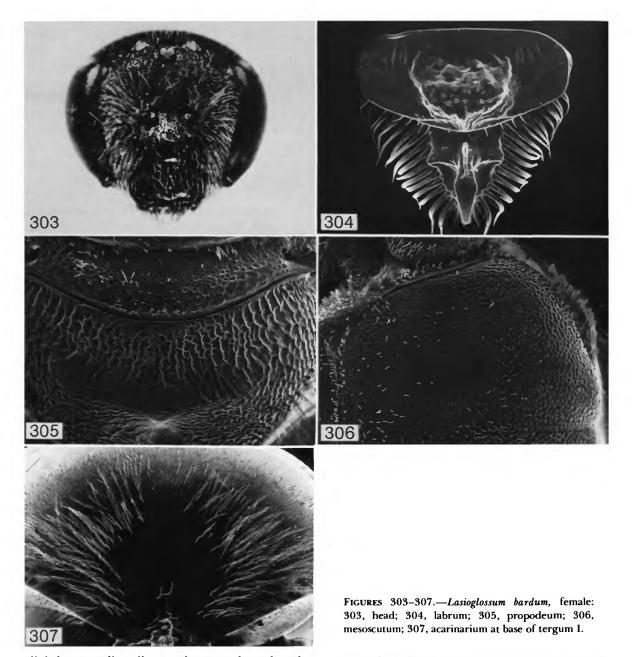

FIGURE 302.—Distribution of Lasioglossum bardum (triangle) and L. desertum (circle).

records from New Mexico and Arizona were most likely based on specimens of *L. morrilli*, which are similar to *L. bardum* and were commonly misidentified by earlier workers. In central Texas, *L. bardum* and *L. morrilli* have contiguous distributions but as yet are not known to be sympatric.

DIAGNOSIS.—The combination of a short head (Figure 303, length/width ratio 0.75-0.92) and hyaline wing membranes will distinguish Lasioglossum bardum from other Lasioglossum species having an acarinarium on the first metasomal tergum I (Figure 307) except for L. jubatum and L. desertum. Lasioglossum jubatum, known from Mexico and southern Arizona, is easily recognized by its deep golden to pale ferrugineous mesoscutal pubescense (white in L. bardum). Lasioglossum desertum is very similar to L. bardum but has a much wider dorsal opening of the acarinarium (opening wider than lateral hair fringe in L. desertum, Figure 393; opening narrower than lateral hair fringe in L. bardum, Figure 307). Lasioglossum morrilli, which also occurs in Texas and is commonly confused with L. bardum, is highly distinctive with an elongate head (Figure 520, length/width ratio 0.86-0.96) and a highly polished, very sparsely punctate clypeus and supraclypeal area (granulate and moderately to densely punctate in L. bardum). The common and widespread species of the forbesii and trizonatum groups have not been collected from Texas. Furthermore, the pale yellowish brown wing membranes and relatively elongate heads of the latter species would distinguish them from L. bardum.

DESCRIPTION.—FEMALE: (1) Length 8.2–10.1 mm ( $\bar{x} = 8.8$ , n = 20); (2) wing length 2.3–2.7 mm ( $\bar{x} = 2.5$ , n = 20); (3) abdominal width 2.6–3.1 mm ( $\bar{x} = 2.8$ , n = 20).

Structure: (4) Head moderately short (Figure 303; length/width ratio 0.75-0.92,  $\bar{x}=0.87$ , n=20). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.73 its length below lower margin of eyes, (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli

slightly exceeding distance between lateral ocellus and eye. (23) Flagellomere 1 shorter than 2 along dorsal surface. Labrum as in Figure 304; (27) distal keel broad as seen in frontal view, widest basally with conspicuous basal median

groove; (28) distal lateral projections very well developed, strongly concave apically; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, interrupted by

oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated. (40) Dorsal surface of propodeum about 0.70 the length of scutellum and about 1.2 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, median portion slightly elevated, lateral rims weakly developed; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 22.

(46) Lateral edge of metasomal tergum II very weakly sinuate, nearly straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area moderately granulate, (52) punctation nearly uniform, punctures 1-2 times their width apart. (53) Clypeus granulate basally, apical half polished (54) punctures well formed basally, separated by less than their width, becoming larger, somewhat obscure and less dense apically, apicolateral areas punctate. (56) Mesoscutum shiny; (57) punctation as in Figure 306, densely punctate laterally and anteriorly, punctures separated by their width or less, becoming more sparsely punctate centrally, punctures separated by 1-4 times their width. (58) Scutellar punctation nearly uniform, similar to that of central area of mesoscutum. (63) Dorsal surface of propodeum rugulose to ruguloso-striolate, striae obscurely reaching posterior margin (Figure 305); (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, most hairs white, dorsal hairs brown basally, becoming light-brown distally. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium present (Figure 307), a large

circular, glabrous area at base of tergum I, surrounded laterally and dorsolaterally by elongate fringe hairs, dorsal opening of acarinarium wide, opening subequal to or wider than width of lateral hair fringe as seen in dorsal view.

FLIGHT RECORDS (Figure 308).—Female *L. bardum* have been collected from late March to late September, with most records from May and June, with a peak in early June.

FLOWER RECORDS.—Females (103): Labiatae 47%; Onagraceae 31%. Total: 103 in 8 families, 10 genera as follows:

\*Agalinis 6(6)\psi; Asclepias 2\psi; Carduus 1\psi; Hymenopappus 1\psi; Lupinus 1\psi; \*Mimosa 2(2)\psi; \*Monarda 48(29)\psi; \*Oenothera 32(29)\psi; \*Opuntia 3(1)\psi; Phacelia 7\psi.

### 8. Lasioglossum cercothrix, new species

FIGURES 23, 309-318

TYPE MATERIAL.—The female holotype of *L. cercothrix*, in the University of California, Davis, is labeled

Mex[ico] 4 mi SE Temoris Chih[uahua] VIII [Aug] 29 1969/ T A Sears R O Gardner C S Glaser/HOLOTYPE Lasioglossum cercothrix R.J. McGinley [red label].

The holotype is in excellent condition. Eight paratypes, including the one known male, are in the University of California, Davis; six at Utah State University, Logan; three at the University of Kansas, Lawrence; and one at Oregon State University, Corvallis.

ETYMOLOGY.—The specific epithet is derived from the Greek *kerkos* (tail) plus *thrix* (hair), a reference to the terminal terga of this species being entirely covered by dense, adpressed pubescence.

DISTRIBUTION (Figure 309).—Lasioglossum

cercothrix is presently known from only 19 females and one male. It appears to be a wide-spread species in Mexico, with current records ranging from Chihuahua south to the state of Puebla.

DIAGNOSIS.—The coarse, contiguous mesoscutal punctation (Figure 313) and the presence of short, adpressed hairs entirely covering terga IV-V (females; similar to Figure 1) and terga IV-VI (males) will distinguish L. cercothrix from all other known New World Lasioglossum. Lasioglossum sandrae, L. crocoturum, and L. tropidonotum are the only other Lasioglossum species having the terminal terga entirely covered by short, adpressed hairs. The latter two species differ from L. cercothrix in having much finer mesoscutal punctuation that is granuloso-punctate throughout (Figure 1) and in having longer heads (Figure 723; L. cercothrix head short, Figure 310). Lasioglossum sandrae is a very different bee, having the mesoscutum entirely covered by short, adpressed pale hairs. Also helpful in recog-

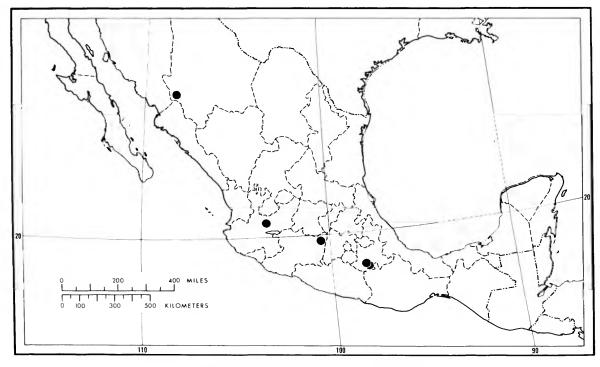

FIGURE 309.—Distribution of Lasinglossum cercothrix.

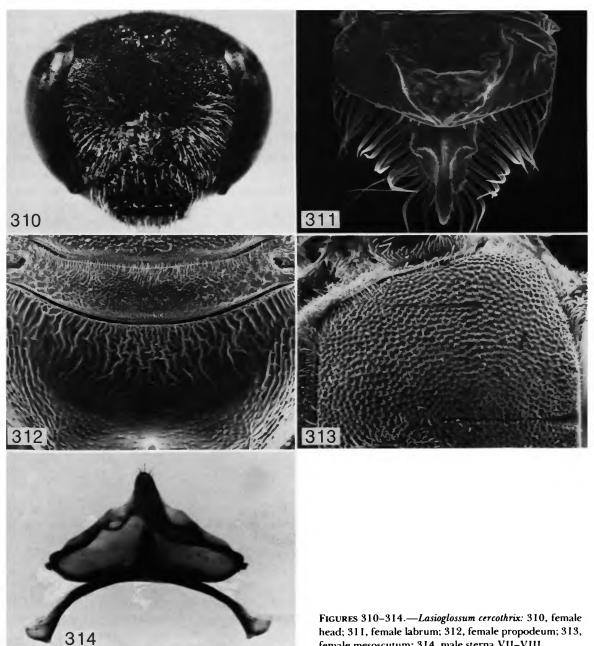

89 NUMBER 429

nizing L. cercothrix is the rounded, relatively smooth and shiny posterior edge of the propodeal dorsal surface (Figure 312).

DESCRIPTION.—FEMALE: (1) Length 8.3–9.8

mm ( $\bar{x} = 8.9$ , n = 15); (2) wing length 2.4-3.0 mm ( $\bar{x} = 2.8$ , n = 15); (3) abdominal width 2.7- $3.0 \ (\bar{x} = 2.9, n = 15).$ 

Structure: (4) Head short (Figure 310;

female mesoscutum; 314, male sterna VII-VIII.

length/width ratio 0.85-0.92,  $\bar{x}=0.88$ , n=15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.69 of its length below lower margin of eyes; (11) surface with median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 311; (27) distal keel moderately broad, lateral edges bowed, with conspicuous basal groove; (28) distal lateral projections moderately well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge weakly edged near oblique sulcus, becoming broadly rounded ventrally. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.78 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle very weakly defined, evident medially as an extremely inconspicuous V-shaped elevation (margin of dorsal surface unusually rounded with no indications of lateral rims); (44) lateral carinae extending approximately twothirds the length of posterior surface. (45) Tibial spur as in Figure 23.

(46) Lateral edge of metasomal tergum II straight, broadly rounded posteriorly.

Sculpture: (47) Face moderately shiny, (48) densely punctate below ocelli, punctures contiguous, becoming only slightly larger and less dense near antennae. (51) Supraclypeal area strigulate; (52) punctures separated by their width or less laterally, becoming sparse centrally. (53) Clypeus obscurely granulate basally, apical two-thirds polished; (54) punctures separated by less than their width, apicolateral areas very sparsely punctate. (56) Mesoscutum moderately dull; (57) punctation as in Figure 313, punctures coarse, dense and nearly contiguous throughout, interspaces granulate. (58) Scutellum nearly uniformly punc-

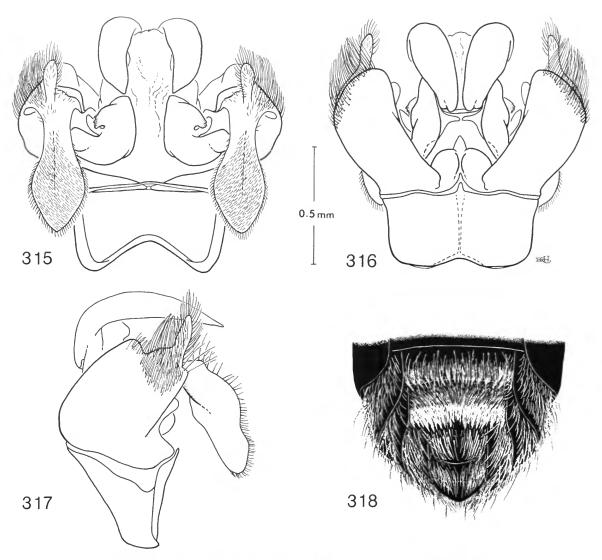

tate, punctures at most separated by their width. (63) Dorsal surface of propodeum (Figure 312) striolate laterally, becoming finely rugulosostriolate medially, posterior edge rounded, somewhat smooth with scattered obscure rugulae; (64) surface not noticeably alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense posteriorly, nearly granuloso-punctate, less dense anteriorly, punctures separated by their width or slightly less.

Coloration: (71) Wing membrane mostly hyaline, lightly infuscated at apex.

Vestiture: (74) Pubescence of head white on gena and near antennae, becoming golden near ocelli and on vertex. (75) Pubescence of thorax mostly white, hairs on mesoscutum and scutellum yellowish brown; (76) mesoscutal hairs moderately dense, simple. (77) Hind tibial hair color differentiated, most hairs white, dorsal hairs light to dark brown. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I. (81) Unlike most other species, basal hair band on tergum II absent, hair band on tergum IV covers entire tergal surface.

MALE: Similar to female except as follows: (1) length 8.2 mm (n = 1); (2) wing length 2.4 mm; (3) abdominal width 2.2 mm. (4) Head short (length/width ratio 0.88). (5) Gena narrower than eye, (6) moderately produced posteriorly. (10) Clypeal surface flat. (24) Labral distal process absent; (25) basal area depressed medially; (26) basal lateral depressions small but distinct. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus weakly granulate throughout, shiny; (54) punctures well formed, nearly contiguous basally, less dense over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 318; (82) hairs on sternum IV moderately elongate, suberect, posterior sternal edge with noticeable fringe of pale hairs; (83) posterior edge of sternum V with conspicuous hair fringe, only indis-

FIGURES 315-318.—Lasioglossum cercothrix, male: 315, genitalia, ventral view; 316, same, dorsal view; 317, same, lateral view; 318, sternal vestiture.

tinctly divided medially into lateral lobes.

Terminalia: Sterna VII-VIII as in Figure 314; (85) sternum VIII with moderately short, narrowly rounded median process. Genitalia as in Figures 315–317; (86) gonobase moderately elongate; (87) gonostylus elongate, slender (unlike other species, gonocoxite hairy distally near

base of gonostylus; (89) retrorse membranous lobe broad near midpoint, tapering apically; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS.—Female records range from late June to late September. The one known male was collected in late August.

FLOWER RECORDS.—Two pollen-laden fe-

males taken from Xanthoxylum (Rutaceae) in the state of Puebla (8 mi SE Tehuitzingo).

#### 9. Lasioglossum channelense, new species

FIGURES 24, 100, 319-331

TYPE MATERIAL.—The female holotype of *L. channelense* is the property of the California Insect Survey, University of California at Berkeley, but is on loan deposit to the California Academy of Sciences in San Francisco. The specimen is in excellent condition and is labeled

Calif[ornia]: Sta. [Santa] Cruz Id. [Island], Ridge S.[outh] of Chinese Harbor VI [ June]-9-1966/R.L. Langston collector/HOLOTYPE Lasioglossum channelense R.J. McGinley [red label].

Two hundred ninety-four paratypes listed in the "Specimens Examined" section are designated.

DISTRIBUTION.—I have seen specimens of L. channelense only from Santa Cruz Island, Santa Barbara County, off the coast of southern California. Rust et al. (1985) report L. trizonatum from Santa Rosa Island. Because L. channelense has long been considered to be a form of L. trizonatum, the Santa Rosa Island specimens are most likely those of L. channelense.

DIAGNOSIS.—Females of *L. channelense* can be recognized by the following character combination: mid and hind tarsi and hind tibiae yellowish orange; acarinarium on anterior surface of tergum I present (Figure 330); pronotal lateral car-

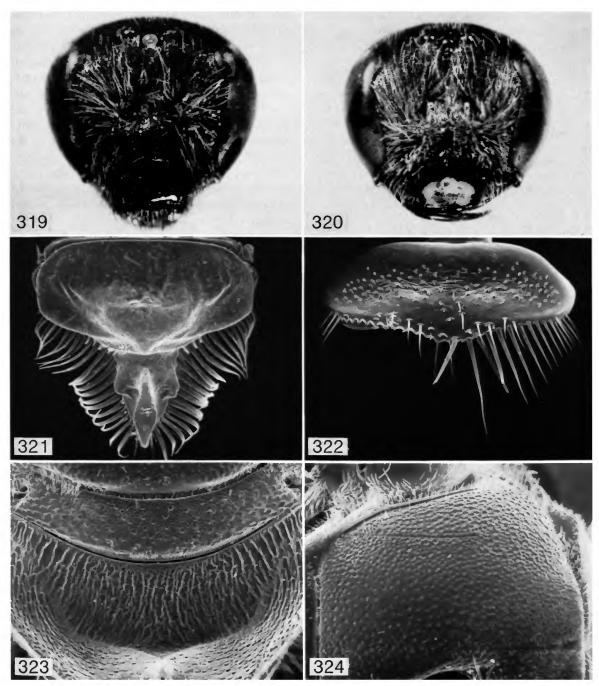

ina virtually complete, at most only inconspicuously interrupted by lateral sulcus (Figure 100); anterior quarter of mesoscutum granulosopunctate (Figure 324). These females are superficially most similar to those of the mainland *L. mellipes*. They differ most conspicuously in having the nearly complete pronotal lateral carina (obviously interrupted in *L. mellipes* and other trizonatum forms, Figure 10) and by having the anterior mesoscutal edge granuloso-punctate (punctures dense but not granuloso-punctate in trizonatum forms, Figure 675). Furthermore, the wing membranes of *L. channelense* are entirely hyaline (slightly yellowish brown in *L. mellipes*).

Males of L. channelense are also similar to those of L. mellipes in having yellowish orange tarsi and erect lateral hair tufts on sternum V (Figure 325) but differ in having a nearly complete pronotal lateral carina, elongate mandibles, which obviously reach beyond the opposing clypeal angles (Figure 320), and shorter heads (Figure 320, length/width ratio  $\bar{x} = 0.93$ , versus Figure 698,  $\bar{x} = 0.97$ ).

DESCRIPTION.—FEMALE: (1) Length 8.6–10.2 mm ( $\bar{x} = 9.7$ , n = 15); (2) wing length 2.6–3.0 mm ( $\bar{x} = 2.8$ , n = 15); (3) abdominal width 2.9–3.2 mm ( $\bar{x} = 3.0$ , n = 15).

Structure: (4) Head moderately elongate (Figure 319; length/width ratio 0.86-1.0,  $\bar{x}=0.93$ , n=15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.95 of its length below lower margin of eyes; (11) surface with obscure median longitudinal sulcation present in most specimens. (14) Distance between lateral ocelli subequal to distance between lateral ocellis and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 321; (27) distal keel broad in frontal view, widest medially; (28) distal lateral projections well developed, rounded; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge superficially appearing complete, interrupted by narrow oblique lateral sulcus; (34) lower portion of lateral ridge elongate and very sharply edged. (35) Mesoscutal lip

FIGURES 319-324.—Lasioglossum channelense: 319, female head; 320, male head; 321, female labrum; 322, male labrum; 323, female propodeum; 324, female mesoscutum.

very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.78 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle very weakly defined laterally, evident medially as a very inconspicuous V-shaped elevation with lateral rims; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 24.

(46) Lateral edge of metasomal tergum II sinuate.

Sculpture: (47) Face shiny, (48) granulosopunctate below ocelli, punctation only slightly less dense near antennae. (51) Supraclypeal area polished; (52) punctures separated by their width laterally, becoming impunctate centrally. (53) Clypeus strongly granulate basally, apical half moderately polished; (54) punctures separated by not more than their width basally, becoming obscurely formed and less dense apically. (56) Mesoscutum shiny; (57) punctation as in Figure 324, punctures dense laterally, contiguous, becoming granuloso-punctate anteriorly, much less dense centrally, punctures 2-3 times their width apart. (58) Scutellum conspicuously doublypunctate, smaller punctures separated by their width or slightly less, larger punctures separated by 2-4 times their width. (63) Dorsal surface of propodeum (Figure 323) ruguloso-granulate; (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline. (72) Unlike most species, mid and hind tarsi, hind tibiae and distal quarter of mid tibiae pale yellowish orange.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white on pronotum and mesopleuron, hairs on mesoscutum and scutellum mostly brown, metanotum with mixture of white and brown hairs; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, most hairs yellowish

brown, dorsal hairs brown to light brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium present (Figure 330), a moderately large glabrous area at base of tergum I, surrounded laterally by moderately sparse, elongate fringe hairs that lack a sharply delimited border; acarinarial surface often with some scattered hairs; dorsal opening of acarinarium moderately wide, not sharply delimited, width slightly less than width of lateral hair fringe as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 7.8–10.0 mm ( $\bar{x} = 8.7$ , n = 15); (2) wing length 2.3–2.7 mm ( $\bar{x} = 2.5$ , n = 15); (3) abdominal width 2.0-2.3 mm ( $\bar{x} = 2.2, n = 15$ ). (4) Head as in Figure 320 (length/width ratio 0.88- $0.96, \, \bar{x} = 0.94, \, n = 15$ ). (5) Gena conspicuously wider than eye, (6) strongly produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 322; (24) distal process weakly to moderately developed, narrowly rounded to somewhat pointed; (25) basal area depressed medially; (26) basal lateral depressions absent. (30) Mandible elongate, reaching midway between opposing clypeal angle and mandibular base. (53) Clypeus polished; (54) punctures well formed and dense along basal

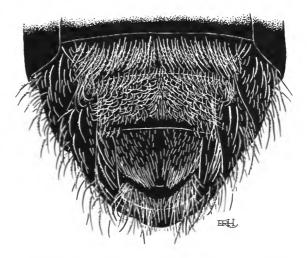

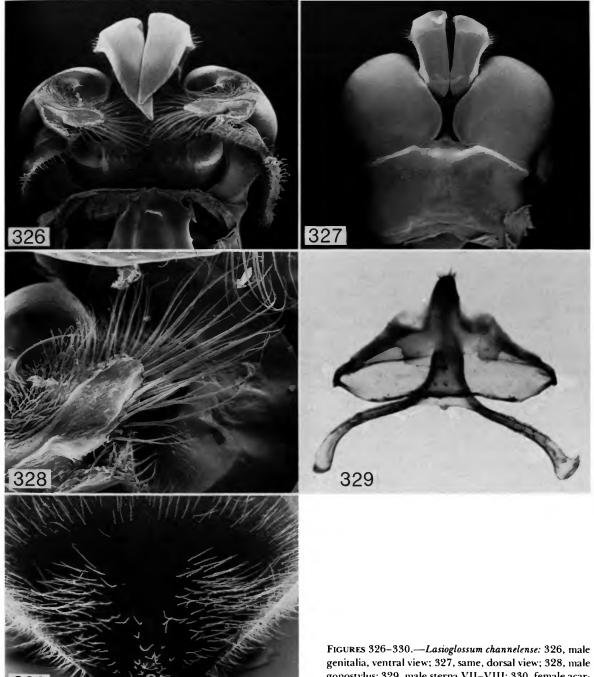

FIGURE 325.—Lasioglossum channelense, male sternal vesti-

gonostylus; 329, male sterna VII–VIII; 330, female acarinarium at base of tergum I.

edge, apical three-quarters virtually impunctate, puncture extremely fine and scattered. (68) Clypeal maculation present (Figure 320). (69) Flagellum only slightly paler ventrally than on dorsum. (72) Tarsi yellowish orange, contrasting with dark tibiae.

Vestiture: Sternal vestiture as in Figure 325; (82) hairs on sternum IV elongate, erect; (83) hairs on sternum V erect, moderately elongate (slightly longer laterally), apices directed laterad from midline.

Terminalia: Sterna VII-VIII as in Figure 329; (85) sternum VIII with short, narrowly rounded median process. Genitalia as in Figures 326–328.

FLIGHT RECORDS (Figure 331).—Females of *L. channelense* have been collected from March through June, with three females from Canada del Medio taken in late September. Most males have been taken in late April through June, with a peak in early May (two males were collected in August and one in September).

FLOWER RECORDS.—Females (15): Cruciferae 40%; Ranunculaceae 33%. Males (5): Rosaceae 80%. Total: 20 in 6 families, 6 genera as follows:

Arctostaphylos 16; \*Brassica 6(6)\(\rap{2}\); \*Cirsium 1(1)\(\rap{2}\); Dendromecon 3\(\rap{2}\); Heteromeles 4\(\rap{3}\); Ranunculus 5\(\rap{2}\).

## 10. Lasioglossum circinatum (Vachal)

FIGURES 25, 258, 332-335

Halictus circinatus Vachal, 1904:474 [female, male].—Cockerell, 1905a:90 [key].

Halictus supercretus Cockerell, 1910a:260 [female; includes comparisons to five other species]; 1910b:284 [probable type-locality Oaxaca, Mexico]; 1918a:179 [comparative taxonomic notes]. [New synonymy.]

Lasioglossum circinatum.—Moure and Hurd, 1986:59 [catalog].

Type Material.—In referring to his original series of Halictus circinatus, Vachal listed "numerous females from Orizaba (Biart 62) and from Mexico (Sichel collection)" (museum notes kindly provided by George C. Eickwort indicate that the female series in the Paris Museum (MNHNP) is comprised of one female labeled "TYPE" and 14 additional females). Vachal also listed two males that he questionably associated with the females. Moure and Hurd (1986) state that "one of the females of the original type series labeled: Orizaba, Biart, was labeled by one of us (Moure) in April, 1958 as the lectoholotype and is now so designated." Only two females from the type series were available for study and the one labeled "TYPE" from the Sichel collection (noted by Eickwort) lacks formal type status. The other specimen from Orizaba (agreeing with Moure's indication) is herein relabeled the lectotype with the designation attributed to Moure to avoid further confusion. The lectotype is missing the distal tarsomere of the right hind leg and has been repinned as evidenced by the pin holes in the thoracic pleura but is otherwise in good condition; it is labeled

MUSEUM PARIS MEXIQUE ORIZABA BIART 1862/14 [?] [18]62 [handwritten on circular label with green under-

surface]/circinatus Q Sichel [handwritten by Vachal?]/LEC-TOTYPE Halictus circinatus Vachal des.[ignated by]

I have attached a paralectotype label to the other female that is still labeled "TYPE."

The two males in Vachal's original series appear to be identical to males known to be associated with *L. acarophilum* in Arizona, where *L. circinatum* does not occur (Figures 245, 258). As Vachal indicated, the association of these males with *L. circinatum* remains doubtful. At present, the males of *L. circinatum* cannot reliably be associated with known females.

The female holotype of *Halictus supercretus* is in the Museum für Naturkunde, Humboldt Universität in Berlin. It is labeled

2583/Mexico [probably Oaxaca, Mexico] [Ferdinand] Deppe [collector]/Type [orange label]/Halictus supercretus Ckll.[Cockerell] TYPE [handwritten by Cockerell]/ Zool.[ogy] Mus[eum] Berlin [yellow label].

Half of the eighth and ninth flagellomeres of the left antenna have been eaten away but the specimen is otherwise in good condition. In his original description of *H. supercretus*, Cockerell (1910a) stated: "Among Vachal's mexican species it [supercretus] comes to the group of *H. crocoturus* &c., but it does not agree with any of his descriptions." This comment clearly indicates that Cockerell did not have any of Vachal's material at hand when he described *H. supercretus*.

DISTRIBUTION (Figure 258).—Lasioglossum circinatum is presently known from only 38 females collected in southern Mexico, from Hidalgo and Michoacan, south to Guatemala (this does not include the additional 13 females in the type series noted by G.C. Eickwort or the two males tentatively associated with this species by Vachal; see above "Type Material" section).

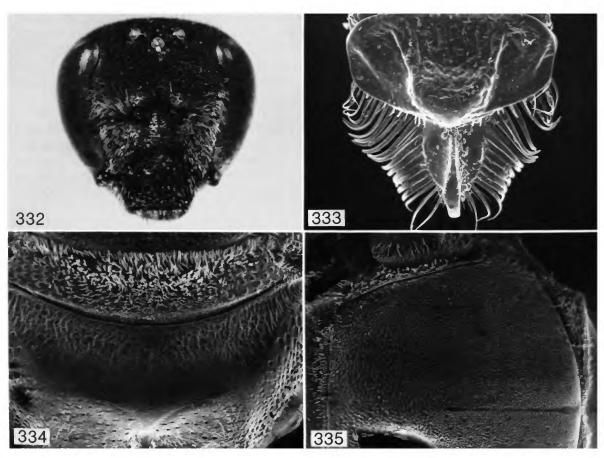

DIAGNOSIS.—Lasioglossum circinatum can be recognized by the following character combination: dorsal surface of propodeum nearly entirely smooth, weakly striolate laterally with very weak median striae confined to basal one-third (Figure 334); acarinarium absent, elongate hairs scattered over anterior surface of tergum I; head elongate (Figure 332, length/width ratio 0.92–

1.03,  $\bar{x} = 0.97$ ). This character combination will distinguish this species from all other New World Lasioglossum except L. pharum and L. troipidonotum. Lasioglossum pharum differs from L. circinatum in having the mesoscutum conspicuously doubly-punctate (Figure 604) and having a polished, shiny clypeal surface (the mesoscutum of L. circinatum is only obscurely doubly-punctate, appearing entirely granuloso-punctate (Figure 335), and its clypeus is entirely dull-granulate with coarse, elongate punctation). Lasioglossum tropidonotum is unique in having a longitudinal median elevation on the anterior edge of the mesoscutum (Figure 174) and has terga IV-V nearly entirely covered by short, adpressed hairs

(normal basal hair bands in *L. circinatum*). Other Mexican species having a dull, smooth dorsal propodeal surface are *L. bajaense* and *L. uyacicola* but these species differ from *L. circinatum* in having metasomal acarinaria. The dorsal proprodeal surface of *Lasioglossum argutum* is smooth over its posterior half but is polished and shiny, not dull. The latter species furthermore has a short head (Figure 262, length/width ratio 0.84-1.0,  $\bar{x}=0.89$ ) and is a much smaller bee (body length 7.1-8.6 vs. 8.4-10.2).

DESCRIPTION.—FEMALE: (1) Length 8.4–10.2 mm ( $\bar{x} = 9.2$ , n = 15); (2) wing length 2.3–3.0 mm ( $\bar{x} = 2.6$ , n = 15).

Structure: (4) Head elongate (Figure 332;

FIGURES 332-335.—Lasioglossum circinatum, female: 332, head; 333, labrum; 334, propodeum; 335, mesoscutum.

length/width ratio 0.92-1.03,  $\bar{x}=0.97$ , n=15). (7) Supraclypeal area evenly rounded ventrally, somewhat narrowly rounded dorsally along frontal carina, (8) moderately protuberant. (9) Clypeus projecting approximately 0.82 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 longer than 2 along dorsal surface. Labrum as in Figure 333; (27) distal keel moderately broad, widest basally; (28) distal lateral projections virtually absent, evident as obscure swellings; (29) most fimbrial setae bluntly rounded.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge somewhat inconspicuous, rounded. (35) Mesoscutal lip very weakly bilobed, (36) weakly elevated from pronotum. (40) Dorsal surface of propodeum about 0.78 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident medially as a very low V-shaped elevation without lateral rims; (44) lateral carinae extending slightly beyond midpoint of posterior surface. (45) Tibial spur as in Figure 25.

(46) Lateral edge of metasomal tergum II very weakly sinuate, nearly straight.

Sculpture: (47) Face dull, granular, (48) doubly-punctate, smaller punctures dense, separated by less than their width, larger punctures separated by 1–2 times their width. (51) Supraclypeal area extremely granulate; (52) uniformly punctate, punctures separated by 1–2 times their width. (53) Clypeus moderately granulate throughout; (54) punctation dense, somewhat coarse, punctures separated by less than their width, becoming elongate apically. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 335, obscurely doubly-punctate, smaller punctures extremely dense, contiguous throughout, larger punctures 3–5 times their width apart (observable at 50 magnifications or more). (58)

Scutellum nearly uniformly punctate, most punctures 1–2 times their width apart, anterior edge with minute, nearly contiguous punctures. (63) Dorsal surface of propodeum (Figure 334) nearly entirely smooth, weakly striolate laterally with very weak median striae confined to basal one-third; (64) surface extensively alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration: (71) Wing membrane mostly hyaline, marginal cell to apex lightly infuscated.

Vestiture: (72) Unlike most species, hairs between vertex and antennae conspicuously simple, recurved, contrasting with pulmose hairs near antennae; (74) pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs inconspicuous, moderately sparse and plumose. (77) Hind tibial hair color differentiated, ventral and lateral hairs white, dorsal hairs dark brown to brown. (78) Anterior hairs of metasomal tergum 1 and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

FLIGHT RECORDS.—Females of *L. circinatum* have been collected in all months except March, April, June, and December.

SPECIMENS EXAMINED.—389.

UNSPECIFIED LOCALITY: 1867 (female paralectotype; MNHNP).

### 11. Lasioglossum citerius (Vachal)

FIGURES 336, 337

Halictus citerior Vachal, 1904:473 [female].—Cockerell, 1905a:90 [key].

Lasioglossum citerius.—Michener, 1951:1106 [catalog].

TYPE MATERIAL.—The femal holotype of *L. citerius* is in the Naturhistorisches Museum, Vienna. It is labeled

Dup.[?] 1845/citerior Vach.[al] det. J. Vachal/Hal.[ictus] \$\fointsilon\text{citerior Vach.[al]/Holotypus [recently handwritten on red label by Ebmer?]/LASIOGLOSSUM \$\fointsilon\text{Lasioglossum citeror}\$ (Vach. 1904) Holotypus, Unicum det. A.W. Ebmer 1980.

The specimen has been repinned as evidenced by the large hole on the right side of the mesoscutal posterior edge and the additional hole in the thoracic venter; the mouthparts, right front tibia and tarsus are obscured by what appears to be hardened nectar; the right antenna and left front leg are missing.

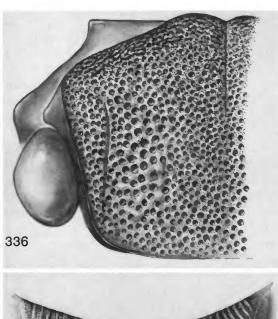

DISTRIBUTION.—Lasinglossum citerius is known only from the unique female holotype, which lacks locality data of any kind. As Vachal (1904) indicated in his original description, the specimen appears to be related to L. pacificum (and related New World species unknown to Vachal). This is tentatively supported by the shape of the head (broad, as in Figure 545), the structure of the lateral pronotal surface (lower portion of pronotal carina broadly rounded, inconspicuous), and sculpture of the propodeal dorsal surface (Figure 337). Furthermore, L. citerius has the unusual dark brown mesoscutal hairs and dark brown hairs on the outer hind tibial surface that are both characteristic of Mexican and Central American Lasioglossum and are not found in species occurring north of the Mexican border. From this I conclude that L. citerius is most likely a Mexican species; however, because of the uncertainty, it has not been treated in the keys.

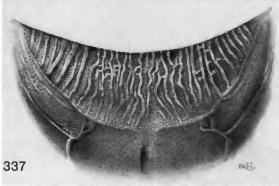

DIAGNOSIS.—The combination of the dark brown mesoscutal hairs and the strongly striate propodeal dorsal surface will distinguish L. citerius from all other New World Lasioglossum except L. orphnaeum. The mesoscutum of L. citerius is granuloso-punctate anteriorly and medially, but unlike L. orphnaeum and all other species, the punctures become conspicuously large and well separated posteriorly (Figure 336; the mesoscutum of L. orphnaeum is nearly entirely granuloso-punctate, Figure 548). Lasioglossum citerius also differs from other species that have a striate dorsal propodeal surface in that the striae, though conspicuous, become weak posteriorly and fail to reach the posterior propodeal margin (Figure 337). Other characters helpful for recognizing L. citerius are the broad head (as in Figure 545), the broadly rounded, inconspicuous lower portion of the pronotal lateral carina (as in L. pacificum and related species) and the sharply pointed pronotal lateral angle (Figure 336).

DESCRIPTION.—FEMALE: (1, 2, 3) Measurements of the holotype were unfortunately not recorded; the specimen is a moderately sized *Lasioglossum*; Vachal (1904) gave 8 mm for the length.

Structure: (4) Head short (as in Figure 545); length/width ratio 0.88 (n = 1). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.50 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. (23, 26, 27, 28) Labrum not examined due to uniqueness of specimen and soiled condition of mouthparts.

(32) Pronotal lateral angle forming well-produced right angle; (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip strongly bilobed, (36) conspicuously elevated

FIGURES 336, 337.—Lasioglossum citerius, female holotype: 336, mesoscutum; 337, propodeum.

from pronotum. (40) Dorsal surface of propodeum about 0.80 the length of scutellum and about I.7 times the length of metanotum, (41) moderately depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle defined by conspicuous but noncarinate lateral rims, median V-shaped area not produced; (44) lateral carinae well developed, not quite reaching dorsal propodeal surface (lateral carinae join conspicuous longitudinal carinae that parallel the dorsal propodeal rim, Figure 337). (45) Tibial spur not removed for study; appears to have one large, conspicuous tooth followed by few, broad, weakly projecting teeth (similar to that of L. argutum, Figure 18).

(46) Lateral edge of metasomal tergum II nearly evenly rounded, only slightly flattened posteriorly.

Sculpture: (47) Face shiny, (48) densely and contiguously punctate below ocelli to antennae. (51) Supraclypeal area conspicuously granulate; (52) punctures obscure, separated by their width. (53) Clypeus granulate basally and medially, apicolateral areas polished; (54) punctures obscure basally, becoming well defined and separated by their width on apical half. (56) Mesoscutum dull anteriorly, shiny on posterior half; (57) punctation as in Figure 336: roughly granuloso-punctate anteriorly and medially, punctures becoming conspicuously large and well separated by at least their width posteriorly. (58) Scutellum granuloso-punctate around margins, less densely punctate adjacent to midline with some punctures separated by their width or slightly more. (63) Dorsal surface of propodeum (Figure 337) strongly striate laterally with striae reaching posterior propodeal margin, striae strong and regular medially over basal three-quarters but become weak and obscure near posterior edge of propodeal dorsal surface; (64) surface appears to be alveolated near posterior edge where striae become obscure. (65) Metasomal tergum I shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane nearly hyaline, very lightly pigmented.

Vestiture: (74) Pubescence of head pale yellowish brown with some dark brown hairs interspersed (especially on vertex). (75) Pubescence of thorax mostly white or off-white, hairs on mesoscutum and scutellum dark brown; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, most hairs white to pale brown, dorsal hairs dark brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I (most of these hairs on the holotype have been worn off).

## 12. Lasioglossum colatum (Vachal), new combination

FIGURES 26, 338-352

Halictus colatus Vachal, 1904:476 [male].—Cockerell, 1907:242 [incorrect synonymy with H. trizonatus]. Halictus ripariellus Cockerell, 1918b:261 [female]. [New

Halictus ripariellus Cockerell, 1918b:261 [female synonymy.]

Lasioglossum ripariellum.—Michener, 1951:1107 [Nearctic catalog].—Hurd, 1979:1958 [Nearctic catalog].

TYPE MATERIAL.—The male holotype of *Halictus colatus* is in the Naturhistorisches Museum, Vienna. It is labeled

Morrison [Jefferson County] Colorado 1879. [indecipherable character]/colatus Vach[al] det. J. Vachal/Hal[ictus] colatus Vach[al] & [handwritten].

The specimen is in fair condition; it is missing the last 10 flagellomeres of the right antenna and has had the head and pronotum glued to the thorax. When received for study in September 1983, the abdomen was loosely connected to the thorax and was secured with a small drop of polyvinyl acetate.

The female holotype of *Halictus ripariellus* is in the California Academy of Sciences, San Francisco. It is labeled

Holotype [on red label]/Florissant [Teller County], Colo.[rado] Expedition 1907. Coll.[ector] Ckll. [Cockerell] June 26/nesting in bank [handwritten by Cockerell]/Halictus ripariellus Ckll. TYPE. [handwritten by Cockerell].

The specimen is missing the last two tarsomeres of the left hind leg and the last tarsomere of the right hind leg but otherwise is in excellent condition.

DISTRIBUTION (Figure 338).—Both Nearctic catalogs reported *Lasioglossum colatum* only from Colorado. It is now known to occur widely in the West from southern British Columbia and Edmonton, Alberta, south to southern Utah and Colorado and through the Sierra Nevada to Alpine County, California. Eastern-most records are from Wyoming and central Colorado, with one female collected from Hanna (Meade Co.), South Dakota, in 1936 (Cornell University Collection).

DIAGNOSIS.—Females of Lasinglossum colatum

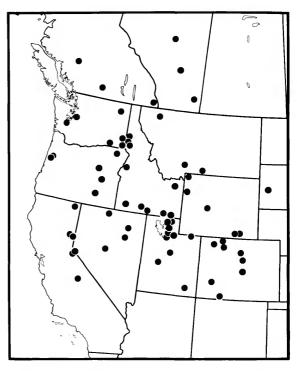

FIGURE 338.—Distribution of Lasinglossum colatum.

can be recognized by their weakly developed but distinctive acarinarium on the anterior surface of the first metasomal tergum (Figure 351): elongate lateral fringe hairs are present but are sparse and form only an indistinct border around the central glabrous area; furthermore, a distinctive patch of short, adpressed hairs is present in the dorsal acarinarial opening. Other characters useful in recognizing L. colatum are the relatively sparse mesoscutal punctation that is obscurely doubly-punctate (Figure 344) and the moderately short head (Figure 339; length/width ratio 0.88-0.96,  $\bar{x} = 0.92$ ). Lasinglossum colatum females are most commonly confused with those of the forbesii and trizonatum groups; however, the acarinarium in the latter species is more strongly developed in having conspicuous lateral hair fringes (Figures 111, 114) and the mesoscutal punctation of both species is denser than that of L. colatum (Figures 439, 675). Lasioglossum forbesii, sensu lato, can further be differen-

tiated from *L. colatum* in having the posterior rim of the dorsal propodeal surface slightly elevated (Figure 438; rounded in *L. colatum*, Figure 343). The elongate heads of *L. trizonatum*, sensu lato, (Figures 683, 709) will readily separate them from *L. colatum*.

The male of Lasioglossum colatum has a round, short head (Figure 340) and a broadly rounded clypeus (not flattened as in most other Lasioglossum males). Also diagnostic is the elongate, slender tergum I as seen from above (Figure 343). Males of L. athabascense also have a rounded head and a rounded clypeus but differ in having long, erect hair tufts on the lateral edges of sternum V (Figure 294).

DESCRIPTION.—FEMALE: (1) Length 7.4–9.8 mm ( $\bar{x} = 8.3$ , n = 15); (2) wing length 2.3–2.7 mm ( $\bar{x} = 2.4$ , n = 15); (3) abdominal width 2.4–2.8 mm ( $\bar{x} = 2.7$ , n = 15).

Structure: (4) Head moderately short (Figure 339); length/width ratio 0.88-0.96,  $\bar{x}=0.92$ , n = 15. (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.84 of its length below lower margin of eyes; (11) surface slightly protuberant towards ventral edge, without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 longer than 2 along dorsal surface. Labrum as in Figure 341; (27) distal keel narrow in frontal view, nearly parallel-sided; (28) distal lateral projections well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.88 the length of scutellum and about 1.7 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin rounded; (43) propodeal triangle weakly impressed, evident medially as an inconspicuous V-shaped elevation with low lateral

rims; (44) lateral carinae extending to midpoint of posterior surface. (45) Tibial spur as in Figure 26.

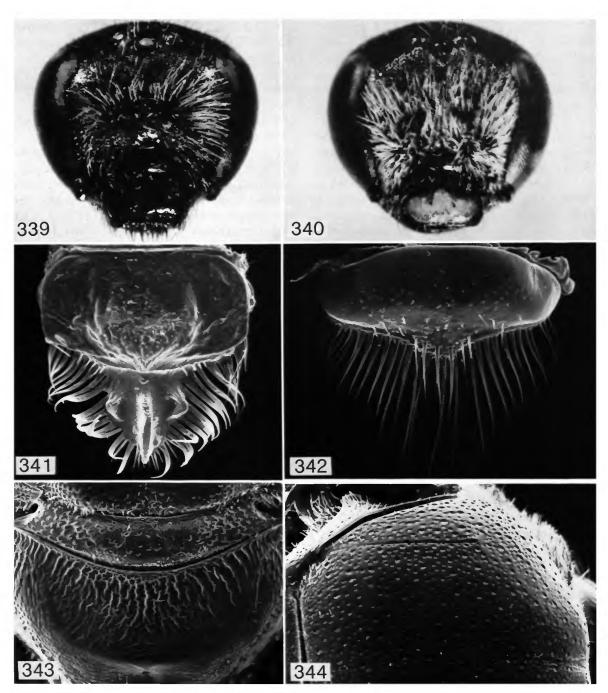

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area very weakly granulate, nearly polished; (52) punctures separated by their width laterally, becoming impunctate centrally. (53) Clypeus polished or at most obscurely granulate over basal third; (54) punctation sparse, punctures separated by 1-2 times their width basally, nearly impunctate apicolaterally. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 344, doubly-punctate, smaller punctures 1-3 times their width apart, larger punctures 3-5 times their width apart, less dense centrally. (58) Scutellum sparsely punctate adjacent to median line, punctures 2–3 times their width apart. (63) Dorsal surface of propodeum (Figure 343) striolate laterally, becoming ruguloso-striolate to finely rugulose medially, striae and rugulae reaching posterior margin; (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane pale yellowish brown.

Vestiture: Pubescence of head pale yellowish brown. (75) Pubescence of thorax white to pale yellowish brown; (76) mesoscutal hairs moderately sparse, not conspicuously plumose. (77) Hind tibial hairs concolorous, pale yellowish brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium present but weakly defined (Figure 351), a small glabrous area at base of tergum I surrounded laterally by scattered elongate hairs, not forming distinct fringe; short, adpressed hairs present dorsolaterally; opening of acarinarium wide, indistinctly defined, wider than lateral hair fringe as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 6.5–8.3 mm ( $\bar{x} = 7.1$ , n = 15); (2) wing

FIGURES 339-344.—Lasioglossum colatum: 339, female head; 340, male head; 341, female labrum; 342, male labrum; 343, female propodeum; 344, female mesoscutum.

length 1.8–2.1 mm ( $\bar{x} = 2.0$ , n = 15); (3) abdominal width 1.8-2.1 ( $\bar{x} = 2.0$ , n = 15). (4) Head as in Figure 340 (length/width ratio 0.86-0.95, x = 0.90, n = 15). (5) Gena slightly wider than eye, (6) moderately produced posteriorly. (10) Clypeal surface noticeably rounded dorsally, contrasting with shallow ventral depression. Labrum as in Figure 342; (24) distal process weakly developed, broadly to narrowly rounded; (25) basal area depressed medially; (26) basal lateral depressions present, moderately developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed and dense along basal edge, apical twothirds virtually impunctate, punctures very fine and scattered. (68) Clypeal maculation present (Figure 340). (69) Flagellum light brown ventrally, contrasting with dark dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 345; (82) hairs on sternum IV erect, longer at midline than laterally; (83) sternum V with median rosette of moderately short, erect hairs that become longer laterally, erect hairs reaching lateral margin of sternum or with erect hairs confined to central portion of sternum.

Terminalia: Sterna VII-VIII as in Figure 350; (85) sternum VIII with short, narrowly

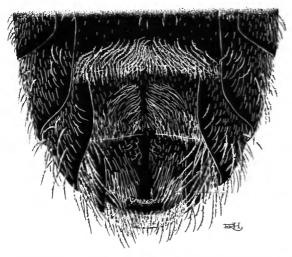

FIGURE 345.—Lasioglossum colatum, male sternal vestiture.

rounded median process. Genitalia as in Figures 346–349; (86) gonobase moderately elongate; (87) gonostylus broad, apex narrowly rounded; (89) retrorse membranous lobe narrow, parallel-sided; (90) volsella with very prominent lateral lobe.

FLIGHT RECORDS (Figure 352).—Lasioglossum colatum females have been collected from March through early October, with most records coming from June and July, with a peak in early July. The one female taken in March was from Franklin County, Idaho (8 Mar 1969); the one October record is from Nez Perce County, Idaho (1 Oct 1944). Males have been taken from July through early September.

FLOWER RECORDS.—Females (21): Compositae 61%; Salicaceae 17%. Total: 21 in six families, eight genera as follows:

Clematis 19; Euphorbia 29; Rosa 19; Rudbeckia 19; Salix 29; Scrophularia 19; Senecio 19; Taraxacum 129.

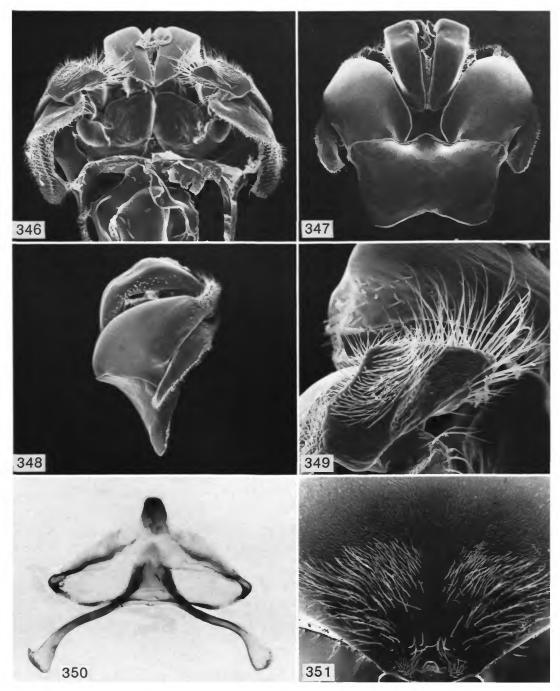

MITE ASSOCIATES.—Although the acarinarium of *L. colatum* is only very weakly developed (Figure 351), 17 (6.8%) of the females examined were associated with phoretic mites.

Halictus coriaceus Smith, 1853:70 [female].—Provancher, 1882:199; 1883:699; 1888:316.—Robertson, 1894:435–480 [flower records].—Dalla Torre, 1896:59 [World catalog].—Cockerell, 1898c:50 [key, taxonomic notes]; 1905b:349 [taxonomic note].—Crawford, 1906:303 [taxonomic notes].—Graenicher, 1906:13 [flower record]; 1907:84–95 [flower records].—Lovell, 1908:34 [locality and flower records].—Graenicher, 1909:19–77 [flower records].—Brittain and Newton, 1933:344 [flower record]; 1934:262 [flower records].—Cockerell, 1949:446 [comparison to H. uyacensis].

Halictus subquadratus Smith, 1853:72 [male].

Halictus 6-cinctus Provancher, 1882:200 [male].
Halictus sexcinctus Provancher.—Dalla Torre, 1896:59
[emendation].

Halicius coniaceus.—Cockerell, 1918b:261 [lapsus calami]. Curtisapis coriacea Robertson, 1918:91 [key].—Reinhard, 1924:371 [predator, Philanthus gibbosus (Fabricius)].—Robertson, 1929 [flower records].

Lasinglossum coriaceum.—Robertson, 1902:247 [key].— Michener, 1951:1106 [Nearctic catalog].—Evans and Lin, 1959:123, 130 [predator, Philanthus gibbosus].—Mitchell, 1960:338, 339, 341 [key, redescription].—Knerer and Atwood, 1962:163 [locality and flower records].—Hurd, 1979:1957 [Nearctic catalog].—Eickwort, 1979:577 [mites].—Hurd et al., 1980:27, 65 [flower records].—Duffield et al., 1981:323 [Dufour's gland chemistry].

TYPE MATERIAL.—The female holotype of Halictus coriaceus is labeled

Type H.T. [circular label with orange-red border]/B.M. TYPE HYM. 14.a.998/B.M. TYPE HYM. Halictus coriaceus Smith 1853 [handwritten]/coriaceus Sm.[Smith] Type [handwritten]/Ent. club 44-12.

The specimen is in poor condition, missing the front left wing, the front and middle legs on the left side as well as the last two tarsomeres of the hind left leg. The left hind wing is partially broken at the base. The holotype is in the British Museum (Natural History).

The male holotype of *Halictus subquadratus*, also in the British Museum, is missing both hind legs beyond the coxae and the distal three tarsomeres of the middle left leg. During shipment in November, 1983, the abdomen broke off behind the first metasomal segment and has been placed in a plastic genitalia capsule attached to the specimen pin. The specimen is labeled.

Type H.T. [circular label with orange-red border]/B.M. TYPE HYM. 17.a.1003/B.M. TYPE HYM. Halictus subquadratus Smith 1853 [handwritten]/subquadratus Sm.[Smith] (Type) [handwritten]/11 [illegible numbers] 490 [handwritten]/Ent. Club. 44 12.

DISTRIBUTION (Figure 353).—Lasioglossum coriaceum is a very common eastern bee found from Cape Breton Island south to northern Georgia and west to Minnesota and eastern Kansas. Three isolated western records are one female from Glenboro, Manitoba (CNC), seven females from Pennington County, South Dakota (AMNH), and one female from Sioux County,

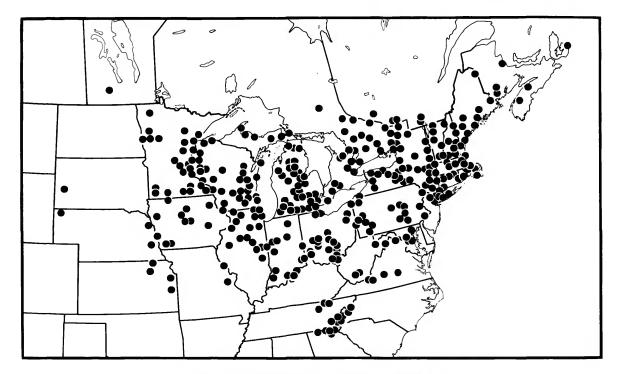

FIGURE 353.—Distribution of Lasioglossum coriaceum.

Nebraska (University of Nebraska). Both nearctic catalogs incorrectly report this species as far west as Alberta and New Mexico; however, these western records are most likely based on misidentifications of *L. forbesii* (sensu lato) and *L. trizonatum* (sensu lato). One male in the USNM labeled "Florida" (no additional data) may be mislabeled.

DIAGNOSIS.—The female of Lasioglossum coriaceum can be distinguished from all other known New World Lasioglossum by the acarinarium on the first metasomal tergum, which is completely enclosed by a circular fringe of elongate hairs (Figure 72). All other species having acarinaria have a dorsal acarinarial opening that is narrow (Figure 408) to very wide (Figure 393). The acarinarium of L. acuminatum is most similar to that of L. coriaceum in being nearly completely enclosed by fringe hairs, but even here there is a very narrow dorsal opening (Figure 407). Another highly diagnostic feature of L. coriaceum is

the very low mesoscutal anterior edge, which is only slightly elevated from the pronotum (as in Figure 87; compare to Figure 90). The only other species having a low mesocutal edge is *L. transvorsum*, a Mexican species that differs from *L. coriaceum* in having a densely granuloso-punctate mesoscutum (Figure 649) and by lacking an acarinarium. Other helpful characters for recognizing *L. coriaceum* females are the smooth posterior half of the dorsal propodeal surface (Figure 358) and the strongly sinuate lateral edge of the second metasomal tergum (Figure 64; a similar tergal edge is found only in *L. anhypops* and *L. trizonatum* from the western United States).

The anterior mesoscutal edge in male *L. coriaceum* is flush with the pronotum and not even slightly raised as in the females. In addition, the males have subquadrate heads with strongly produced genae and extremely elongate mandibles that reach the opposing mandibular bases. In the eastern United States only the male of *L. acumi-*

natum has similar elongate mandibles that are slightly shorter than those of L. coriaceum, reaching just short of the opposing mandibular bases. However, Lasioglossum acuminatum has an elevated mesoscutal edge and yellow tarsi (tarsi dark, concolorous with the tibiae in L. coriaceum).

DESCRIPTION.—FEMALE: (1) Length 8.3–11.2 mm ( $\bar{x} = 9.8$ , n = 20); (2) wing length 2.7–3.1 mm ( $\bar{x} = 2.9$ , n = 20); (3) abdominal width 2.6–3.5 mm ( $\bar{x} = 3.0$ , n = 20).

Structure: (4) Head elongate (Figure 354); length/width ratio 0.89-1.0,  $\bar{x}=0.94$ , n=34. (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus strongly projecting below lower margin of eyes by approximately 0.86 of its length; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 356; (27) distal keel moderately broad in frontal view, slightly wider basally; (28) distal lateral projections moderately well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip rounded, not bilobed, (36) very weakly elevated from pronotum. (40) Dorsal surface of propodeum about 0.89 the length of scutellum and about 1.7 times the length of metanotum, (41) not noticeably depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, median portion not elevated, lateral rims absent; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 27.

(46) Lateral edge of metasomal tergum 11 very strongly sinuate (Figure 64).

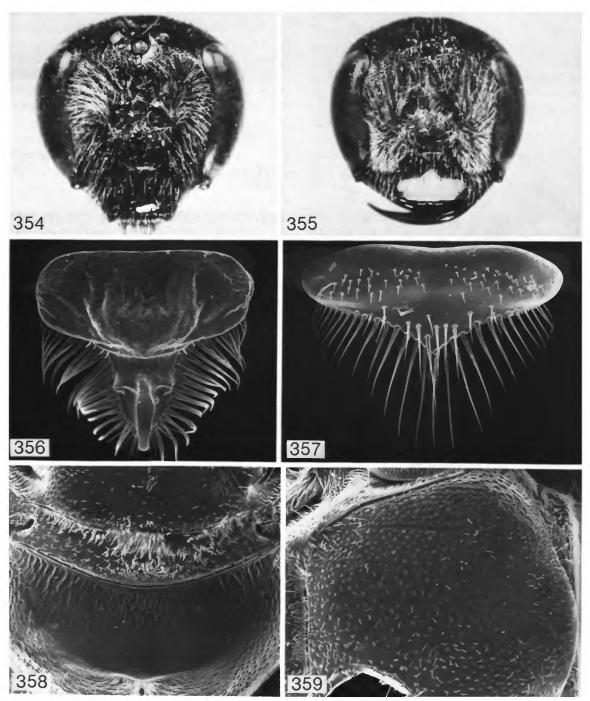

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area polished, (51) punctures separated by their width laterally, separated by 2-4

times their width centrally. (53) Clypeus polished; (54) punctures well formed, separated by their width or less along basal edge, becoming sparse centrally, separated by 1-2 times their width, apical edge and apicolateral areas largely impunctate. (56) Mesoscutum dull (57) punctation as in Figure 359, punctures variable in size, not distinctly doubly-punctate; punctures separated by their width laterally, becoming less dense anteriorly and centrally, punctures separated by 1-4 times their width. (58) Scutellum sparsely punctate adjacent to median line, punctures separated by 2-3 times their width. (63) Dorsal surface of propodeum incompletely striolate, striae reaching posterior surface laterally, confined to basal one-third medially (Figure 358); (64) surface alveolated. (65) Metasomal tergum 1 moderately shiny; (66) punctation fine, dense, punctures slightly less than their width

Coloration: (71) Wing membrane light yellowish brown, somewhat clearer towards apex.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax mostly pale yellowish brown, white on pronotal lateral angle, pronotal lobe, and metanotum; (76) mesoscutal hairs moderately sparse and plumose. (77) Hind tibial hairs concolorous, yellowish brown. (78) Anterior hairs of metasomal tergum I pale yellowish brown, (79) basal hair bands of terga 11–IV white. (80) Acarinarium present (Figure 72), a relatively small circular, glabrous area at base of tergum I, completely encircled by elongate fringe hairs, dorsal opening of acarinarium absent.

MALE: Similar to female except as follows: (1) length 6.8–9.8 mm ( $\bar{x}=8.1$ , n=20); (2) wing length 1.8–2.5 mm ( $\bar{x}=2.3$ , n=20); (3) abdominal width 1.8–2.8 mm ( $\bar{x}=2.1$ , n=20). (4) Head as in Figure 355 (length/width ratio 0.83–0.96,  $\bar{x}=0.93$ , n=20). (5) Gena wider than eye, (6) strongly produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 357; (24) distal process present, developed as a flat, acute projection; (25) basal area weakly depressed medially; (26) basal lateral

FIGURES 354-359.—Lasioglossum coriaceum: 354, female head; 355, male head; 356, female labrum; 357, male labrum; 358, female propodeum; 359, female mesoscutum.

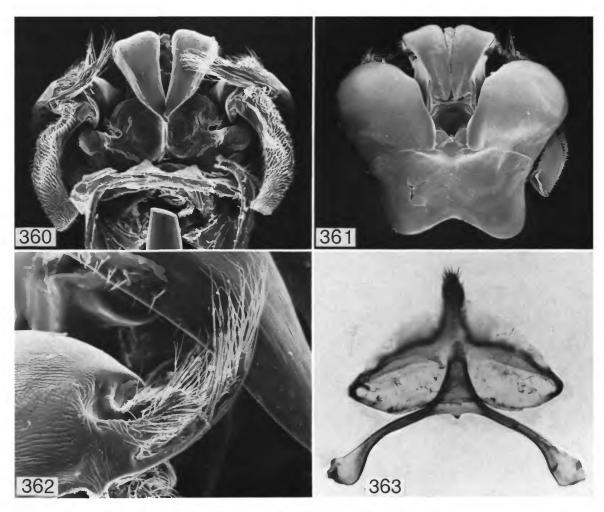

NUMBER 429 Il11

depressions absent. (30) Mandible extremely elongate, reaching opposing mandibular base. (53) Clypeus polished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present (Figure 355). (69) Flagellum entirely dark or with ventral surface slightly paler than dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: (82) Hairs on sternum IV erect, elongate, longer at midline than laterally; (83) sternum V with relatively inconspicuous median

rosette of short erect hairs, posterior edge of sternum with short, broadly rounded, adpressed hair lobes.

Terminalia: Sterna VII-VIII as in Figure 363; (85) sternum VIII with short, narrowly rounded median process. Genitalia as in Figures 360–362; (86) gonobase moderately elongate; (87) gonostylus moderately broad basally, gradually tapering to acute apex; (89) retrorse membranous lobe moderately broad; (90) volsella with very prominent lateral lobe.

FIGURES 360-363.—Lasioglossum coriaceum, male: 360, genitalia, ventral view; 361, same, dorsal view; 362, gonostylus; 363, sterna VII-VIII.

FLIGHT RECORDS (Figure 364).—Lasioglossum coriaceum females have been collected from the second half of March through early October, with most records from late June. Virtually all male records are from July through October. Unusual records are as follows: one male from Rockville, Pennsylvania, 25 May 1910; one male from Dorset, Ontario, 21 May 1961; two in June (Mattituck, New York, 4 Jun 1934; Hemmingford, Quebec, 24 Jun 1916) and one in November (Great Falls, Virginia, 10–18 Nov 1978). In the northern part of the species distributionrange, male records peak in early September, whereas males to the south peak in the second half of August.

FLOWER RECORDS.—Floral data indicates that L. coriaceum is broadly polylectic. Hurd et al. (1980) have reported this species as being a "cas-

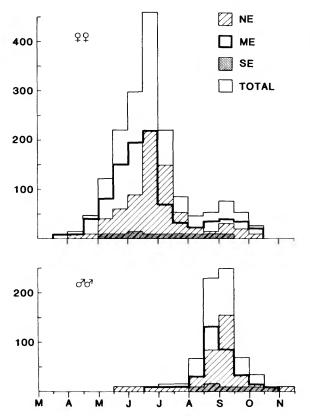

FIGURE 364.—Lasioglossum coriaceum flight records.

ual polylege" of *Helianthus*. The 332 females examined in this study that had associated floral data were taken nearly equally from flowers of the Compositae, Cruciferae, Leguminosae, and Rosaceae. These four families accounted for 71% of all female flower records; 46 females were noted to have full to nearly full pollen loads and these were taken from flowers representing six families.

Summary: Females (332): Rosaceae 22%; Compositae 17%; Cruciferae 16%; Leguminosae 15%. Males (71): Compositae 80%; Rosaceae 10%. Total: 403 in 30 families, 69 genera as follows:

Alliaria 29; Allionia 119; Althaea 19, 18; Amelanchier 29; Amorpha 19; Anaphalis 19; Angelica 19; Apocynum 39; Arctium 19; Asparagus 19; Aster 69, 116; \* Barbarea 37(11)9; \* Brassica 13(2)\(\mathbb{2}\); Camassia 1\(\mathbb{2}\); Campanula 2\(\mathbb{2}\); Capsella 1\(\mathbb{2}\); Castanea 19; Ceanothus 59; Cichorium 39; Cirsium 19; Cornus 29; Crataegus 19; Daucus 16; \* Echium 5(3)9; Erigeron 39; 26; Eryngium 19; Eupatorium 26; Forsythia 19; Geranium 39; Helianthus 29; 18; Hieracium 89; \* Houstonia 2(2)9; \* Hydrangea 1(1)9; Hydrophyllum 19; Leontodon 29; Lonicera 19; Malva 18; Medicago 39; 18; Melilotus 419, 28; \* Pastinaca 1(1)9; Pentstemon 19; Philadelphus 39; Phlox 19; Physocarpus 19; Polemonium 39; Polygonum 18; \* Potentilla 19(13)9; Prunus 69; Pyrus 109; 75; Ranunculus 29; \* Rhus 13(5)9; \* Rosa 19(2)\(\mathbb{2}\); \* Rubus 15(5)\(\mathbb{2}\); Rudbeckia 3\(\mathbb{2}\), 3\(\dagge\); Salix 9\(\mathbb{2}\); Saliva 1\(\mathbb{2}\); Solidago 159, 376; Sonchus 49, 18; Sorbaria 29; Spirea 59; \* Taraxacum 6(1)9; \* Trifolium 6(1)9; Tussilago 39; Vaccinium 49; Veronica 29; Veronicastrum 18; Viburnum 39; Viola 39; Zizia 2Q.

MITE ASSOCIATES.—Of the 1786 females examined, 1356 (76%) had hypopodes in their acarinaria. This is in general agreement with Eickwort's (1979) estimate that "85% of museum specimens bear anoetid hypopodes." Two hundred eighty-three (43%) of the 656 males examined carried hypopodes on their ventral surface, usually from the venter of the thorax to the front coxae and genae (rarely on the mandibles).

Specimens Examined.—2442 (17869, 6568).

#### 14. Lasioglossum costale (Vachal)

FIGURES 28, 365-371

Halictus costalis Vachal, 1904:475 [female].—Cockerell, 1905a:90 [key].

Halictus matensis Friese, 1916:303 [female]. [New Synon-ymy.]

Lasioglossum costale.—Moure and Hurd, 1986:60 [catalog].

TYPE MATERIAL.—Vachal based his description of *Halictus costalis* on four syntypic females deposited in the Paris Museum (MNHNP). Moure and Hurd (1986) state that "one of the females of the original type series (collection Sichel) was labeled by one of us (Moure) in April, 1958 as the lectoholotype and is now so designated." This specimen now lacks the lectoholotype label mentioned above and instead has a

large red "HOLOTYPE" label. In order to avoid additional confusion I have reattached a lectotype label with the designation attributed to Moure. The lectotype is in good condition, missing only the last two tarsomeres of the left hind leg and most of the mesoscutal hairs. It is labeled

MUSEUM PARIS Mexique [handwritten] COLL. O. SICHEL 1867/HOLOTYPE [handwritten on red label]/costalis 9 Vach.[al] [handwritten by Vachal?]/Halictus costalis Vach. [handwritten]/LECTOTYPE Halictus costalis Vachal des.[ignated by] Moure [red label; labeled by McGinley, 1984].

I have attached yellow "PARALECTOTYPE" labels to the three remaining females in Vachal's original series.

Friese based his description of *H. matensis* on two females from San Mateo, Costa Rica. The one specimen available for study is herein designated the lectotype; it is labeled

Costa Rica San Mateo 1904/Halictus matensis ? 1915 Friese Fr. det./Typus [square orange label]/Zool. Mus. Berlin/LECTOTYPE Halictus matensis des.[ignated by] McGinley.

The lectotype is missing the left antenna but

otherwise is in excellent condition. It is deposited in the Museum für Naturkunde der Humboldt-Universität zu Berlin.

DISTRIBUTION (Figure 365).—Lasioglossum costale has been collected from Costa Rica, Guatemala, Honduras, and the Mexican states of Michoacan, Veracruz, and Chiapas. Only 22 females and 6 males are currently known.

DIAGNOSIS.—The combination of the entirely granuloso-punctate mesoscutum (similar to Figure 649; not coarse as in L. cercothrix, Figure 313), ruguloso-striolate dorsal propodeal surface (as in Figure 1), the absence of a metasomal acarinarium and the lack of conspicuous infuscation along the anterior edge of the forewing will distinguish the females of L. transvorsum, L. costale, L. manitouellum, L. asaphes, and L. xyriotropis from those of other New World Lasioglossum. Lasioglossum transvorsum is easily recognized by the elevated, V-shaped propodeal rim (Figure 650) and the distinctive, adpressed hair patches on the anterior surface of tergum I (Figure 651). The pronotal lateral carina of L. asaphes and L. xyriotropis is complete (Figures

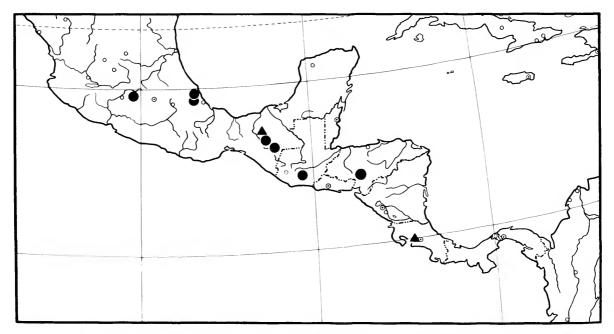

FIGURE 365.—Distribution of Lasioglossum costale, light form (circle) and dark form (triangle).

280, 732), whereas that of *L. costale* and *L. manitouellum* is distinctly interrupted by a lateral sulcus. This interruption is broad and conspicuous in *L. costale* (Figure 281) versus narrow yet distinct in *L. manitouellum*. The latter species has hyaline forewing membranes with lightly infuscated apices (Figure 152), whereas the wings of *L. costale* are pale orange throughout.

Most females of *L. costale* have pale yellowish brown mesoscutal pubescence and distinctive pale yellowish orange hind tibiae. However, three females, including both types, have dark brown mesoscutal hairs and dark brown tibiae (see "Remarks" section).

The males of *L. costale* can be recognized by the vestiture of sternum V, which is characterized by a dense rosette of short hairs on the posterior edge that expands into lateral lobes of relatively long hairs (Figure 371).

DESCRIPTION.—FEMALE: (1) Length 7.8–9.3 mm ( $\bar{x} = 8.6$ , n = 13); (2) wing length 2.3–2.6 mm ( $\bar{x} = 2.5$ , n = 13); (3) abdominal width 2.3–2.9 mm ( $\bar{x} = 2.7$ , n = 13).

Structure: (4) Head short (similar to Figure 303); length/width ratio 0.83-0.92,  $\bar{x}=0.89$ , n = 13. (7) Supraclypeal area slightly narrowly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.85 of its length below lower margin of eyes; (11) surface apparently without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 366; (27) distal keel moderately narrow in frontal view, nearly parallel-sided; (28) distal lateral projections somewhat small but distinct, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse, pointed; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.84 the length of scutellum and about 1.6 times the length of metanotum,

FIGURES 366, 367.—Lasioglossum costale: 366, female labrum; 367, male sterna VII-VIII.

(41) depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident medially as a low V-shaped elevation, lateral rims absent; (44) lateral carinae extending approximately one-third the length of posterior surface. (45) Tibial spur as in Figure 28.

(46) Lateral edge of metasomal tergum II very weakly sinuate.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area strigulate; (52) obscurely and sparsely punctate,

punctures separated by 1-5 times their width. (53) Clypeus granulate basally, apical two-thirds moderately polished; (54) punctures obscure basally, large and elongated apically, separated by their width or less. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 649, punctures extremely dense, contiguous throughout, becoming granuloso-punctate anteriorly. (58) Scutellum granuloso-punctate posteriorly, punctures less dense and larger anteriorly adjacent to median line, separated by 1-2 times their width. (63) Dorsal surface of propodeum completely ruguloso-striolate (similar to Figure I); (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration: (71) Wing membrane deep yellowish orange, becoming infuscated apically.

Vestiture: (74) Pubescence of head yellowish brown near antennae, becoming gold-brown on vertex (brown on vertex in three females). (75) Pubescence of thorax mostly pale yellowish brown, white on pronotal lateral angle and pronotal lobe (mesoscutal hairs brown in three females); (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, ventral hairs golden, dorsal hairs brown (hairs mostly dark brown in three females). (78) Anterior hairs of metasomal tergum I pale yellowish brown, (79) basal hair bands of terga II—IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I

MALE: Similar to female except as follows: (I) length 6.4–8.0 mm ( $\bar{x}=7.2$ , n=3); (2) wing length 2.0–2.2 mm ( $\bar{x}=2.1$ , n=3); (3) abdominal width 1.8–2.I mm ( $\bar{x}=2.0$ , n=3). (4) Head moderately elongate (length/width ratio 0.9I–0.95,  $\bar{x}=0.92$ , n=3). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. (24) Labral distal process absent; (25) basal area depressed medially; (26) basal lateral depressions weakly developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate basally, apical two-thirds polished; (54)

punctures well formed, nearly contiguous basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

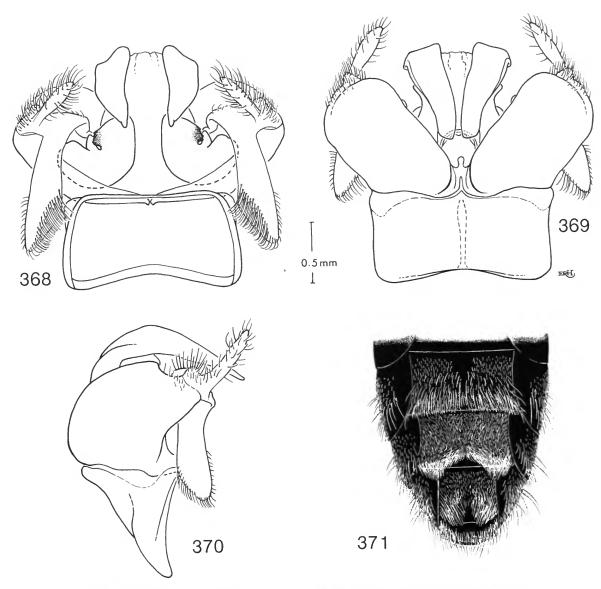

Vestiture: Sternal vestiture as in Figure 37 I; (82) hairs on sternum IV moderately short, suberect to erect; (83) hairs on sternum V very short, suberect, posterior edge of sternum with median rosette of short, dense hairs that expand laterally into moderately elongate hair lobes.

Terminalia: Sterna VII-VIII as in Figure 367; (85) sternum VIII with short, broadly rounded median process. Genitalia as in Figures 368–370; (86) gonobase moderately elongate; (87) gonostylus extremely elongate and slender; (89) retrorse membranous lobe moderately broad with characteristic hair patch along apical margin; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS.—Lasing lossum costale females have been collected in every month except January, August, and November. The six known males have been taken from early March through May.

FLOWER RECORDS.—One pollen-laden female taken from *Bidens pilosa* (Compositae) in Michoacan, Mexico.

REMARKS.—The lectotype females of both Halictus costalis Vachal and H. matensis Friese have dark brown mesoscutal hairs and dark brown hind tibiae. Only one other "dark form" female from Simojovel, Chiapas, is known. Vachal's syntype series of four females included two with pale yellowish brown mesoscutal pubescence and yellowish orange hind tibiae that were labeled "H.[alictus] costalis var.[iety]." In his original description Vachal lists these specimens as representing a variety of H. costalis with "translucent posterior tibiae." It is this "light form" of Lasioglossum costale that has been most commonly collected. Considerable variation exists in the pigmentation of hind tibiae; in fact, one of the females Vachal grouped with the one "dark form" female in his series actually has light brown tibiae and pale yellowish brown mesoscutal pubescence characteristic of the "light form."

FIGURES 368-371.—Lasioglossum costale, male: 368, genitalia, ventral view; 369, same, dorsal view; 370, same, lateral view; 371, sternal vestiture.

Nevertheless, the possibility exists that these two forms represent distinct species, but aside from the color differences mentioned above, the only detected morphological difference is that the posterior margin of the dorsal propodeal surface is more sharply edged in the "dark form" females.

Furthermore, one male collected on 18 Mar 1953, in the vicinity of a "dark form" female taken on 19 Mar 1953 near Simojovel, Chiapas, appears to be identical with other males associated with "light form" females.

Vachal ended his treatment of Halictus costalis

by indicating that the species (or possibly just the "light form" females) may prove to be conspecific with *H. politus* Smith, 1879 (preoccupied by *politus* Schenck, 1853) (= *H. schenckii* (Ritsema)). Type material of *H. schenckii* or presumed conspecific specimens could not be located for study. Smith's description is very generalized but he does mention that the wings of *H. schenckii* are pale fulvo-hyaline, and Cockerell (1898c, 1905b) states that the wings are "strongly yellowish." This sounds similar to the condition found in *L. costale* but cannot be determined in the absence of type material. *Lasioglossum schenckii*, herein treated as a nomen dubium, would have priority if shown to be conspecific with *L. costale*.

# 15. Lasioglossum crocoturum (Vachal), new combination

FIGURES 1, 29, 372-380

Halictus crocoturus Vachal, 1904:473 [female, male].—Cockerell, 1905a:90 [key].

Halietus sericeus Friese, 1916:304 [female]. [New synonymy.]

Type MATERIAL.—Vachal did not designate a holotype for *Halictus crocoturus*; his description

was based on two females and one male. The one syntypic female available for study is herein designated the lectotype. It is labeled

Museum Paris, MEX1QUE, Coll. O. Sichel 1867/Mex[ico], [illegible word, presumably the collector name], [18]67 [handwritten]/HOLOTYPE[handwritten on red label]/crocoturus Vach[al] ? [handwritten]/Halictus crocoturus Vach.[al] [handwritten]/LECTOTYPE Halictus crocoturus Vachal des.[ignated by] McGinley.

The lectotype is in good condition but has many hairs on the head and thorax matted, an old pin-hole on the left side of the propodeum and has evidence of old mold growth on the antennae. The lectotype, male paralectotypes and presumably the female paralectotype are deposited in the Paris Museum (MNHNP).

The female holotype of *H. sericeus* could not be located for study. See "Remarks" section for explanation of synonymy.

DISTRIBUTION (Figure 372).—Lasioglossum crocoturum is known from only I0 females and five males ranging from the Mexican states of Nayarit, Michoacan, and Oaxaca, south to Guatemala, El Salvador, and Panama.

DIAGNOSIS.—Females and males of *L. crocoturum* can be distinguished from all other known *Lasioglossum* by the following combination: tergum IV nearly entirely covered by short, pale, adpressed pubescence (Figure I; not the usual basal hair band) and the anterior edge of the forewing, including the marginal cell, conspicuously infuscated (Figure I). Tergum III of *L. crocoturum* females is unique in having two transverse bands of pale, adpressed pubescence (Figure I). Other characters helpful in recognizing *L. crocoturum* are the finely granuloso-punctate mesoscutum and the dense, conspicuous hair patches covering the pronotal lateral angle (Figure 1).

Other species having tergum IV covered by adpressed pubescence are L. tropidonotum and L. cercothrix. The former has a distinctive median longitudinal ridge on the mesoscutum (Figure 174) and lacks an infuscated wing pattern. Lasioglossum cercothrix has only the apex of the forewing infuscated (the marginal cell is hyaline). Furthermore, L. cercothrix has a coarsely punc-

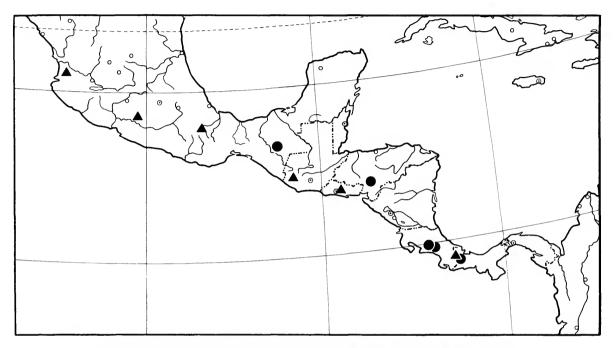

FIGURE 372.—Distribution of Lasioglossum crocoturum (triangle) and L. uyacicola (circle).

tate mesoscutum (Figure 313; finely granulosopunctate in *L. crocoturum*, Figure 1) and has a short head (Figure 310, length/width ratio 0.85– 0.92; elongate in *L. crocoturum*, length/width ratio 0.88–0.96). *Lasioglossum sandrae* also has tergum IV covered by short, adpressed pubescence but is a much larger bee (body length 9.8– 11.1, vs. 7.8–9.6) and has the mesoscutum conspicuously covered by short, suberect pubescence (mesoscutal hair elongate, erect in *L. crocoturum*).

DESCRIPTION.—FEMALE: (1) Length 7.8–9.6 mm ( $\bar{x}=7.5,\ n=7$ ); (2) wing length 2.4–2.7 mm ( $\bar{x}=2.6,\ n=7$ ); (3) abdominal width 2.4–3.0 mm ( $\bar{x}=2.8,\ n=7$ ).

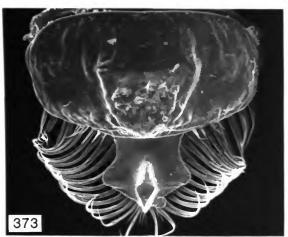

Structure: (4) Head elongate; length/width ratio 0.88-0.96,  $\bar{x}=0.92$ , n=7. (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.82 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli slightly exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 373;

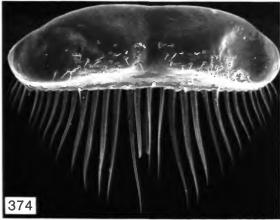

(27) distal keel moderately broad, short; (28) distal lateral projections very well developed, conspicuously broad, rounded; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, narrowly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded to sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.65 the length of scutellum and about 1.1 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle very weakly defined laterally, evident medially by low, rounded Vshaped elevation without lateral rims; (44) lateral carinae extending approximately three-fourths the length of the posterior surface, nearly reaching the dorsal propodeal surface. (45) Tibial spur as in Figure 29.

(46) Lateral edge of metasomal tergum II very weakly sinuate.

Sculpture: (47) Face moderately shiny, (48)

FIGURES 373, 374.—Lasioglossum crocoturum labra: 373, female; 374, male.

densely and nearly uniformly punctate between ocelli and antennae, punctures contiguous and only slightly larger near antennae. (51) Supraclypeal area extremely granulate; (52) punctures separated by their width or less. (53) Clypeus granulate basally, apical half polished; (54) punctures separated by less than their width basally, less dense and larger on apical half. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 1, punctures extremely dense, finely granuloso-punctate throughout. (58) Scutellum nearly uniformly granuloso-punctate, some punctures slightly separated near center. (63) Dorsal surface of propodeum (Figure 1) rugu-

loso-striolate; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) granuloso-punctate throughout.

Coloration: (70) Posterior two-thirds of wing membrane mostly hyaline, anterior one-third along costal margin, including marginal cell, strongly infuscated.

Vestiture: (74) Pubescence of head golden (pale yellowish brown in specimens from Michoacan). (75) Pubescence of mesoscutum golden, hairs on pronotal lateral angle and metanotum vellowish white (specimens from Michoacan with mesoscutal hairs pale yellowish brown, pronotal and metanotal hairs white); hairs on pronotal lateral angle thick, conspicuous; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, most hairs white, dorsal hairs light brown to brown. (78) Anterior hairs of metasomal tergum I white; (78) hair bands of terga II-IV yellowish white (white in specimens from Michoacan). (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I. (80) Tergum III with two transverse, adpressed hair bands; tergum IV-V entirely covered by short, adpressed pubescence (Figure 1).

MALE: Similar to female except as follows: (1) length 7.2-8.5 mm ( $\bar{x} = 8.0$ , n = 3); (2) wing length 2.1-2.3 mm ( $\bar{x} = 2.2$ , n = 3); (3) abdominal width 1.9-2.0 ( $\bar{x} = 2.0$ , n = 3). (4) Head elongate (length/width ratio 0.95-0.96,  $\bar{x} =$ 0.96, n = 3). (5) Gena slightly wider than eye, (6) well produced posteriorly. (10) Clypeal surface flat, only faintly depressed near apical margin. Labrum as in Figure 374; (24) distal process absent; (25) basal area depressed medially; (26) basal lateral depressions faint to well developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus weakly granulate basally, apical two-thirds polished; (54) punctures well formed, nearly contiguous basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 375; (82) hairs on sternum IV moderately short and

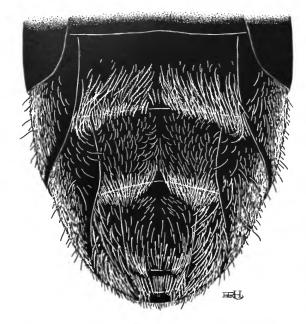

FIGURE 375.—Lasioglossum crocoturum, male sternal vestiture.

suberect to erect medially, becoming noticeably longer and erect laterally; (83) sternum V without conspicuous erect hairs, posterior edge of sternum with broadly rounded, adpressed hair lobes.

Terminalia: Sterna VII-VIII as in Figure 380; (85) sternum VIII with short, broad, apically rounded median process. Genitalia as in Figures 376–379; (86) gonobase moderately elongate; (87) gonostylus broad basally, tapering to narrowly rounded apex; (89) retrorse membranous lobe enormously broad; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS.—Females of *L. crocoturum* have been collected in February, March, late May, and late September. All known male records are from March.

REMARKS.—I have not seen the type of *Halictus sericeus* Friese (it could not be found in the Berlin Museum (ZMHU) where it presumably was deposited). In his original description, Friese mentions that the third tergum of *H. sericeus* has two transverse bands of short, adpressed hairs and that the fourth tergum is entirely covered

by similar pubescence. He also notes the infuscated anterior margin of the forewing. This character combination is unique to *L. crocoturum* (Vachal), and I therefore feel confident in synonymizing both names. Furthermore, I have a specimen before me from Guatemala identified as *H. sericeus* (apparently identified by Cockerell) that is clearly conspecific with the type of *H. crocoturus*.

Hair coloration is highly variable among specimens of *L. crocoturum*. Most specimens of *L. crocoturum* (including the lectotype) have generally golden pubescence with the hairs on the pronotal lateral angles, metanotum, and abdominal terga distinctly yellowish white. All of the specimens examined from Michoacan, Mexico, have conspicuously white pubescence. This variation is possibly clinal with paler forms occurring in the northern portion of the species range; however, because of the paucity of material this cannot presently be determined.

#### 16. Lasioglossum desertum (Smith)

FIGURES 30, 302, 381-394

Halictus desertus Smith, 1879:38 [female, male].—Fox, 1893:14 [locality record: Baja California?].—Dalla Torre, 1896:60 [World catalog].—Cockerell, 1897:164 [taxonomic notes]; 1899:5 [locality record]; 1905b:353 [taxonomic notes].—Sandhouse and Cockerell, 1924:333 [distribution].—Cockerell, 1949:446 [taxonomic notes].

Halictus dersertus.—Dalla Torre, 1896:60 [lapsus calami]. Halictus cyaneiceps Cockerell, 1916a:254 [female, male]; 1930:6 [relationship to H. heterorhinus]. [New synonymy.] Lasioglossum cyaneiceps.—Michener, 1951:1106 [Nearctic

catalog].—Hurd, 1979:1957 [Nearctic catalog]. Lasioglossum desertum. - Michener, 1954:40 [compared to L. uyacicola].

Type Material.—Smith based his original

ostylus; 379, volsella; 380, sterna VII-VIII.

description of Halictus desertus on a female and male from Oajaca (sic), Mexico. The female lectotype, herein designated, is in poor condition. The hairs on and around the scutellum are soiled

and the specimen is missing the following parts: the left antenna; tarsus and tibia of the left foreleg; distal tarsomere of the right foreleg; two distal tarsomeres of the left middle leg; tarsus and femur of the left hind leg; tarsus of the right hind leg. The lectotype, in the British Museum (BMNH), is labeled

Type H.T. [circular label with orange border]/B.M. TYPE HYM. 17.a.1012/Halictus desertus (Type) Sm. [handwritten]/LECTOTYPE Halictus desertus Smith des.[ignated by] McGinley.

The temale holotype of *Halictus cyaneiceps*, in the National Museum of Natural History, Smithsonian Institution, is in excellent condition except for missing the last tarsomere of the left hind leg. It is labeled

Coll.[ector] Townsend/White Mts[Mountains] 7[Jul] 31 NM[New Mexico]/Rio Ruidoso [Lincoln County] Abt[about] 6500ft/On fls[flowers of] Heliopsis scabra/Type No. 20407 U.S.N.M.[red label]/Halictus cyaneiceps Ckll.[Cockerell] ? TYPE [handwritten by Cockerell].

Four female paratypes have been located: two in the National Museum of Natural History, one in the Canadian National Collection, and one in the University of California, Berkeley.

DISTRIBUTION (Figure 302).—Lasioglossum desertum occurs throughout the Rocky Mountain system as far north as Musselshell County, Montana, south to the state of Oaxaca, Mexico. Most specimens, however, have been collected in Arizona, Colorado, and New Mexico. Label data often includes elevation information with figures ranging from 5400 to 8750 feet. One male, possibly mislabeled, was collected from Murray County, Oklahoma (University of Kansas Collection).

DIAGNOSIS.—The short head (Figure 381; length/width ratio 0.78-0.92,  $\bar{x}=0.86$ ), hyaline wing membranes and presence of an acarinarium on the anterior surface of metasomal tergum I (Figure 393) will separate female L. desertum from other Lasioglossum species except L. bardum and L. jubatum. Lasioglossum jubatum also has an extremely wide dorsal acarinarial opening (Figure 478), which differs from the relatively narrow opening found in L. bardum (Figure 307).

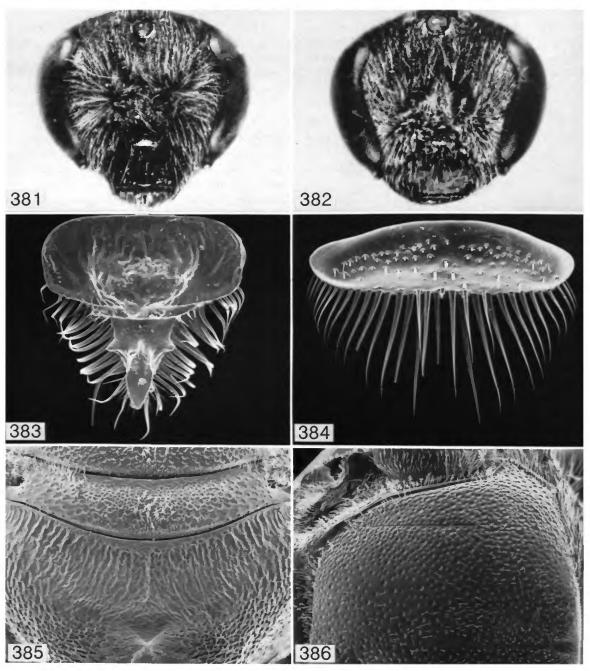

Lasioglossum jubatum can be easily recognized by the deep golden to pale ferrugineous mesoscutal pubescence (white in L. desertum). Lasioglossum acarophilum (from Mexico and southern Arizona) and L. uyacicola (from Chiapas, Mexico to Panama) also have very wide dorsal acarinarial openings but have relatively elongate heads (Figures 246, 724) and mesoscuta that are completely granuloso-punctate and doubly-punctate (Figures 251, 727), differing from the relatively sparse punctation on the posterior half of the L. desertum mesoscutum (Figure 386).

Males of *L. desertum*, like those of *L. heterorhinum* and *L. lampronotum*, have conspicuously broad heads (Figures 382, 459, 487). The latter two species have complete pronotal lateral carinae, whereas that of *L. desertum* is distinctly interrupted. The hair lobes on the posterior edge of sternum V are only narrowly separated medially (Figure 387; compare with those of *L. heterorhinum*, Figure 464). Furthermore, the gonostyli of *L. heterorhinum* and *L. lampronotum* are only moderately elongate (Figure 468) differing from the conspicuously elongate gonostylus of *L. desertum* (Figure 391).

DESCRIPTION.—FEMALE: (1) Length 7.4–9.9 mm ( $\bar{x} = 8.6$ , n = 20); (2) wing length 2.3–2.6 mm ( $\bar{x} = 2.5$ , n = 20); (3) abdominal width 1.8–2.9 mm ( $\bar{x} = 2.6$ , n = 20).

Structure: (4) Head short (Figure 381; length/width ratio 0.78-0.92,  $\bar{x}=0.86$ , n=20). (7) Supraclypeal area evenly rounded, (8) very weakly protuberant. (9) Clypeus projecting approximately 0.71 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 383; (27) distal keel broad in frontal view, somewhat spoon-shaped; (28) distal lateral projections well developed, triangular, and sharply pointed; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (35) Mesoscutal lip

FIGURES 381-386.—Lasioglossum desertum: 381, female head; 382, male head; 383, female labrum; 384, male labrum; 385, female propodeum; 386, female mesoscutum.

weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.76 the length of scutellum and about 1.3 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, median V-shaped area inconspicuous, lateral rims absent; (44) lateral carinae extending less than half the length of posterior surface. (45) Tibial spur as in Figure 30.

(46) Lateral edge of metasomal tergum II weakly sinuate, nearly straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming only slightly larger and less dense near antennae. (51) Supraclypeal area extremely granulate, (51) uniformly punctate, punctures 1-2 times their width apart. (53) Clypeus granulate basally, apical half polished; (54) punctures somewhat obscure, nearly contiguous basally, larger and less dense apically, apicolateral areas sparsely punctate. (56) Mesoscutum shiny; (57) punctation as in Figure 386, punctures separated by their width or less laterally, becoming granulopunctate anteriorly, less dense centrally, punctures separated by 1-4 times their width. (58) Scutellum sparsely punctate adjacent to median line, punctures 1-3 times their width apart. (63) Dorsal surface of propodeum (Figure 385) ruguloso-striolate, striae obscurely reaching posterior margin; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense, conspicuously plumose. (77) Hind tibial hairs concolorous, pale yellowish brown. (78) Anterior hairs of metasomal tergum 1 and (79) basal hair bands of terga I1–IV white. (80) Acarinarium present (Figure 393), a large circular, glabrous area at base of tergum I, surrounded laterally and dorsolaterally by elongate hair fringes, dorsal opening of acarinarium wide, opening slightly wider than width of lateral hair

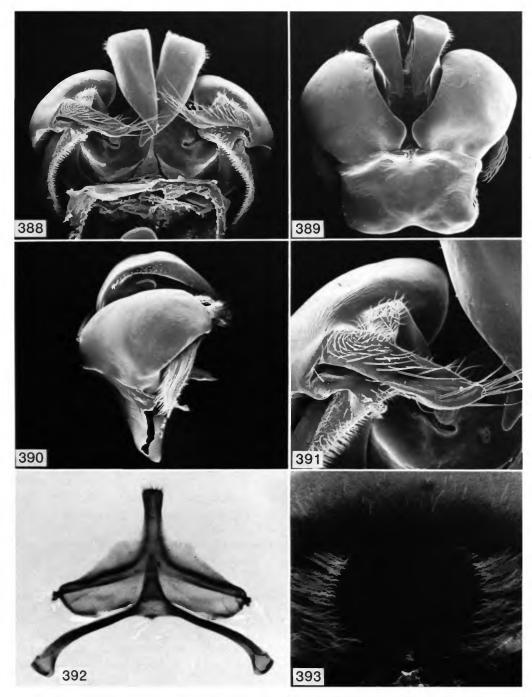

fringe as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 6.4-8.1 mm ( $\bar{x} = 7.4$ , n = 20); (2) wing length 1.8–2.3 mm ( $\bar{x} = 2.1$ , n = 20); (3) abdominal width 1.6-2.1 mm ( $\bar{x} = 1.8$ , x = 20). (4) Head as in Figure 382 (length/width ratio 0.76-0.95,  $\bar{x} = 0.86$ , n = 20). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 384; (24) distal process absent; (25) basal area depressed medially; (26) basal lateral depressions absent. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum pale yellowish orange ventrally, strongly contrasting with dark dorsum or entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 387; (82) hairs on sternum IV elongate, erect; (83) sternum V without conspicuous erect hairs, posterior edge of sternum with broadly rounded, moderately elongate and narrowly separated lat-

FIGURE 387.—Lasioglossum desertum, male sternal vestiture.

FIGURES 388-393.—Lasioglossum desertum: 388, male genitalia, ventral view; 389, same, dorsal view; 390, same, lateral view; 391, male gonostylus; 392, male sterna VII-VIII; 393, female acarinarium.

eral adpressed hair lobes.

Terminalia: Sterna VII-VIII as in Figure 392; (85) sternum VIII with extremely elongate, slender median process, slightly broader apically than along stem. Genitalia as in Figures 388–391; (86) gonobase moderately elongate; (87) gonostylus extremely elongate and slender; (89) retrorse membranous lobe slender; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS (Figure 394).—Lasioglossum desertum females have been collected from late March through early November, with most records (82%) from June through August, with a peak in late July. The March and September records are from southern Arizona. The two October records are from San Luis Potosi and Jalisco, Mexico; the November record from Pima County, Arizona. Most males have been collected in August but records range from June through September.

FLOWER RECORDS.—Females (38): Cucurbitaceae 13%; Scrophulariaceae 13%; Compositae 11%. Males (34): Compositae 71%; Labiatae

24%. Total: 72 in 18 families, 28 genera as follows:

Arctostaphylos 19; Aster 22&; Baccharis 1&; Ceanothus 39; Cucurbita 19; Engelmannia 1&; Erigeron 19; Geranium 29, 2&; Heliopsis 29; Heterotheca 19; Ipomoea 29; Iris 1(1)9; \*Malvastrum 1(1)9; Marrubium 19; \*Melilotus 2(1)9; Monarda 8&; Penstemon 29; Physocarpus 29; \*Pulsatilla 1(1)9; Rhus 19; Rubus 19; \*Salix 1(1)9; Schinus 19; Sicyos 49; Sisyrinchium 19; Sphaeralcea 29; Verbascum 39; Vitis 19.

REMARKS.—Cockerell saw the type of Halictus desertus in the British Museum shortly before 1905 and published a short descriptive account of this specimen (Cockerell, 1905b). Eleven years later in his description of H. cyaneiceps (Cockerell, 1916), Cockerell compared this new species to H. bardus, H. forbesii, and H. trizonatus but made no mention of H. desertus. Cockerell later republished his notes on the Smith type (Cockerell, 1949) but it is apparent he never compared H. cyaneiceps, which he described from New Mexico, with H. desertus (described from Oaxaca, Mexico).

A number of male specimens examined in the present study appeared to be similar to those of L. desertum but differed in having slightly longer heads and more noticeable lateral hair lobes along the posterior edge of sternum V (similar to those of L. argutum, Figure 268). These may be shown to be the males of L. rupticristum (see L. rupticristum "Remarks" section for further details).

### 17. Lasioglossum eickworti, new species

FIGURES 32, 395-405

TYPE MATERIAL.—The holotype female is deposited in the Cornell University Insect Collection. It is labeled

EL SALVADOR Cerro Verde 1 Oct 1977 P. Bernhardt MH68 [?]/HOLOTYPE Lasioglossum eickworti R.J. McGinley [red label].

The holotype is missing the right antenna, the

distal 9 flagellomeres of the left antenna, and the distal tarsomere of the right hand leg but is otherwise in good condition. Ten female and four male paratypes, listed in the "Specimens Examined" section, are in the collections of Cornell University, Canadian National Collection (Ottawa), and the Los Angeles County Museum.

ETYMOLOGY.—This species is named after G.C. Eickwort (Cornell University), who generously provided me with most of the specimens available for study, and who greatly aided this project with many detailed discussions of halictine systematics.

DISTRIBUTION (Figure 395).—Lasioglossum eickworti is presently known from only 11 females and four males. These specimens have been collected from Chiapas, Mexico, south to Guatemala, El Salvador, and Costa Rica.

DIAGNOSIS.—The large size (length 9.5–10.7 mm,  $\tilde{x} = 10.0$ ), slender body form, sharply-edged and produced upper portion of the pronotal

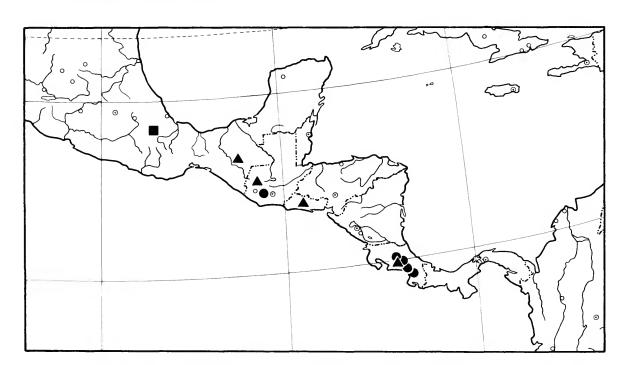

FIGURE 395.—Distribution of Lasioglossum eickworti (triangle), L. katyae (circle), and L. sandrae (square).

lateral carina (Figure 405), infuscated anterior edge of the forewing (as in Figure 1), distinctive dorsal propodeal surface (elongate and narrowly rounded posteriorly), and characteristic short, adpressed hairs on the anterior surface of metasomal tergum I will distinguish the females of *L. eickworti*, *L. sandrae*, and *L. katyae* from those of all other New World *Lasioglossum*. These three species apparently form a natural group as evidenced by the presumed apomorphic characters listed above.

Lasioglossum sandrae is easily differentiated from L. eickworti and L. katyae and other New World Lasioglossum in having the mesoscutum and metasomal terga 1V-V covered by short, adpressed, pale hairs. The only other Lasioglossum species having terga 1V-V entirely covered by adpressed, pale pubescence are L. tropidonotum, L. cercothrix, and L. crocoturum. The latter species are much smaller than L. sandrae and lack adpressed mesoscutal hairs. Lasioglossum sandrae also has a unique transverse depression near the apical clypeal edge.

Unlike L. sandrae, L. eickworti and L. katyae have relatively elongate, dark brown to black mesoscutal hairs. The latter two species can be differentiated on the basis of mesoscutal punctation. The mesoscutum of L. eickworti is entirely granuloso-punctate, becoming scabrous anteriorly, whereas that of L. katyae is uniformly doubly-punctate with the smaller punctures being much finer than those of L. eickworti.

Of the three species, only males of *L. eickworti* are known. In addition to the female diagnostic characters listed above, these males are unusual in having extremely elongate mandibles that reach the opposing mandibular bases and strongly produced, tuberculate genal lobes, which are unique among New World *Lasioglossum* (Figure 401).

DESCRIPTION.—FEMALE: (1) Length 9.5-10.7 mm ( $\bar{x} = 10.0$ , n = 6); (2) wing length 3.0-3.2 mm ( $\bar{x} = 3.1$ , n = 6); (3) abdominal width 2.8-2.9 mm ( $\bar{x} = 2.9$ , n = 6).

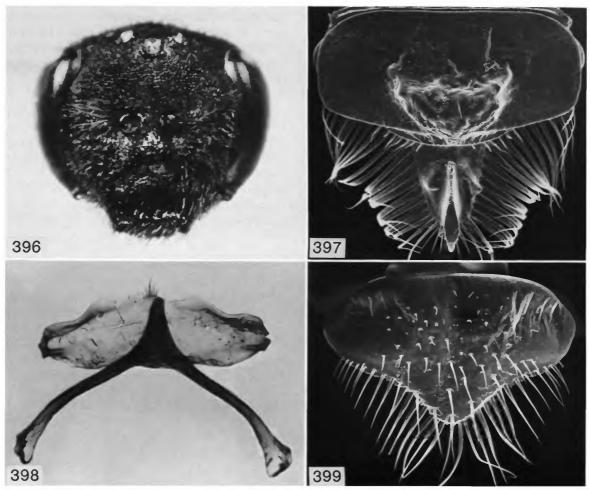

Structure: (4) Head moderately short (Figure 396; length/width ratio 0.85–0.96,  $\tilde{x} = 0.89$ , n

= 6). (7) Supraclypeal area narrowly rounded dorsally near well-developed carina, (8) area strongly protuberant. (9) Clypeus projecting approximately 0.92 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 397; (27) distal keel moderately broad, lateral edges bowed; (28) distal lateral projections small but distinct, conical; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle very narrowly obtuse, sharply pointed; (33) pronotal lateral ridge incomplete, very narrowly interrupted by oblique lateral sulcus; (33) upper portion of lateral ridge strongly carinate, lower portion broadly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.78 the length of scutellum and about 1.6 times the length of metanotum, (41) not depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle well defined by carinate rim (V-shaped medial impression and lateral rims not elevated); (44) lateral carinae extending approximately two-thirds the length of posterior surface. (45) Tibial spur as in Figure 32.

(46) Lateral edge of metasomal tergum II broadly convex anteriorly, straight posteriorly.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) uniformly punctate, punctures separated by 1–3 times their width. (53) Clypeus granulate over basal one-third, obscurely granulate over apical two-thirds; (54) punctures separated by less than their width basally, separated by 1–2 times their width on apical two-thirds. (56) Mesoscutum moderately dull; (57) doubly-punctate, smaller punctures extremely dense, contiguous throughout, larger punctures separated by 2–4 times their width. (58) Scutellum nearly uniformly punctate, punctures separated at most by their width. (63) Dor-

FIGURES 396-399.—Lasioglossum eickworti: 396, female head; 397, female labrum; 398, male sterna VII-VIII; 399, male labrum.

sal surface of propodeum striolate laterally, ruguloso-striolate medially, striae and rugulae reaching posterior margin laterally and along median line, propodeum smooth adjacent to median line; (64) surface obscurely alveolated. (65) Metasomal tergum I moderately dull; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration: (70) Posterior half of wing membrane lightly infuscated to hyaline, anterior one-third to one-half deeply infuscated.

Vestiture: (74) Pubescence of head mostly

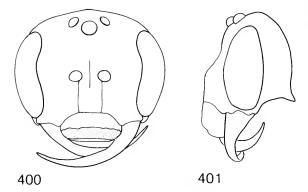

dark brown, pale brown on postgena, some whitish hairs near antennal sockets. (75) Pubescence of thorax mostly dark brown, hairs white on pronotal lobe and propodeum, some white hairs on metanotum; (76) mesoscutal hairs short, moderately dense and plumose. (77) Hind tibial hairs concolorous, dark brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium apparently absent, anterior surface of tergum I with short, adpressed hairs surrounded laterally by elongate hairs. (81) Unlike most species, hair

bands of terga 11-111 narrow, covering at most basal 0.25 of terga, tergum IV hair band absent.

MALE: Similar to female except as follows: (I) length 8.7-10.1 mm ( $\bar{x} = 9.3$ , n = 3); (2) wing length 2.6-2.7 mm ( $\bar{x} = 2.6, n = 3$ ); (3) abdominal width 1.9-2.1 mm ( $\bar{x} = 2.0$ , n = 3). (4) Head as in Figure 400 (length/width ratio 0.85-0.92,  $\bar{x} = 0.88$ , n = 3). (5) Gena wider than eye, (6) strongly produced posteriorly with conspicuous angulate projection (Figure 401). (10) Clypeal surface rounded. Labrum as in Figure 399; (24) distal process moderately long, narrowly rounded; (25) basal area depressed medially; (26) basal lateral depressions conspicuously developed. (30) Mandible extremely elongate, reaching opposing mandibular base. (53) Clypeus strongly granulate along basal edge, apical twothirds polished; (54) punctation somewhat uniform, apical punctures larger and less dense than basal punctures. (68) Clypeal maculation present (Figure 400). (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: (82) Hairs on sternum IV moderately short, suberect; (83) hairs on sternum V short, sternum without noticeable hair patterns or lobes (very faint suggestion of lateral hair lobes on posterior sternal edge).

Terminalia: Sterna VII-VIII as in Figure 398; (85) sternum VIII without median process. Genitalia as in Figures 402-404; (86) gonobase very short; (87) gonostylus very robust, rounded

FIGURES 400, 401.—Lasioglossum eickworti, male head: 400, frontal view; 401, lateral view.

apically; (89) retrorse membranous lobe inconspicuous, extremely reduced and slender; (90) volsella extremely reduced, lacking lateral lobe (the penis valves of *L. eickworti* differ greatly from those of other New World *Lasioglossum* species in being highly angulate and sharply edged).

FLIGHT RECORDS.—Females of *L. eickworti* have been collected in June through early October, with most records (5) from October. One male was collected in April, two others were taken in August.

REMARKS.—One female specimen in the collection of the University of California, Berkeley, bears the following label:

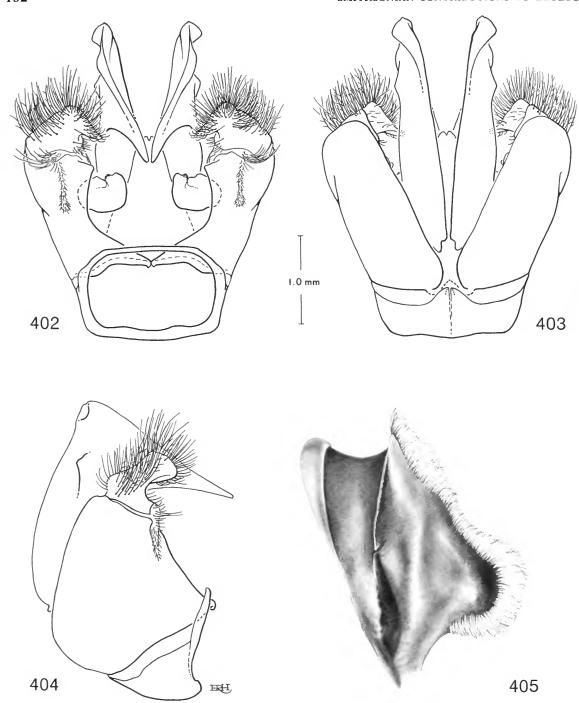

n.g. [new genus]? nr. [near] Lasioglossum det. G.C. Eickwort.

Indeed, L. eickworti, L. sandrae, and L. katyae share numerous characters (listed in the above diagnosis) that appear to set them off as a natural group. In addition, the genitalia of the L. eickworti male is extremely different from that of all other known New World Lasioglossum (Figures 402-404; males of L. sandrae and L. katyae are not known). I originally considered recognizing this group as a distinct genus but now think this would be premature. Through the kindness of Laurence Packer (University of Toronto), I was able to examine genitalic preparations of many Old World Lasioglossum species. The diversity of genitalic structure in this material is high (much greater than is found among New World species) and some are at least superficially similar to the genitalia of L. eickworti. Because of this I hesitate to accord these three New World forms even subgeneric status at present. Such a designation may prove to be desirable but should await a rigorous phylogenetic review of both New and Old World Lasioglossum.

#### THE forbesii GROUP

SPECIES INCLUDED.—Lasioglossum acuminatum, new species; L. forbesii (Robertson); L. paraforbesii, new species.

DISTRIBUTION (Figure 406).—The forbesii

group is widespread throughout much of Canada and the United States, occurring from New Brunswick to Alberta and Idaho and south to New Mexico, Oklahoma, Arkansas, and North Carolina.

DIAGNOSIS.—The females of the forbesii group all have slightly elevated lateral rims on the posterior margin of the dorsal propodeal surface. This will separate them from other females that have an acarinarium on the anterior surface of tergum I, especially those of the trizonatum group and L. colatum. The acarinarium of L. acuminatum is highly distinctive in being arrow-shaped (Figure 407), and that of L. forbesii is also diagnostic in having only a very narrow dorsal open-

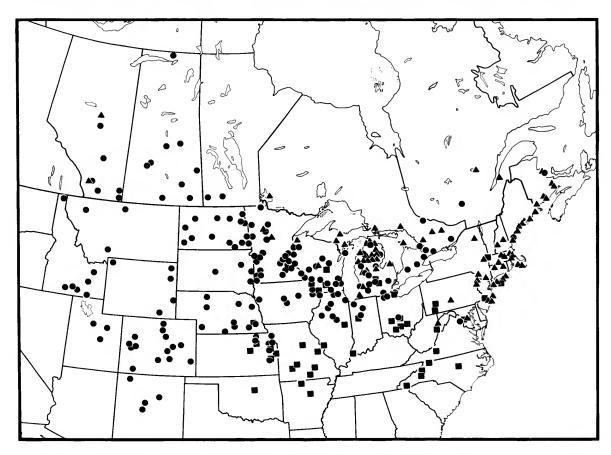

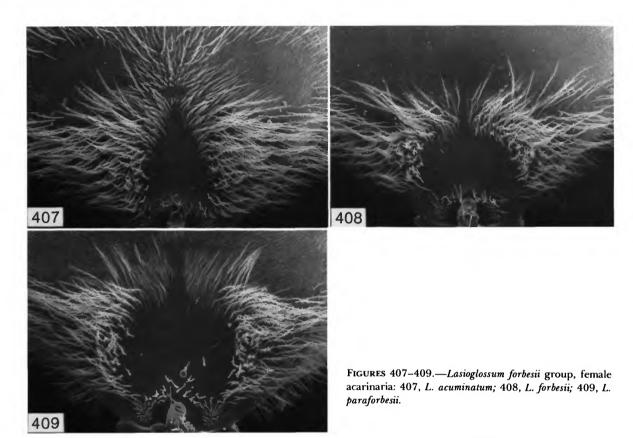

FIGURE 406.—Distribution of Lasioglossum forbesii group: L. acuminatum (triangle), L. forbesii (square), L. paraforbesii (circle).

ing to the hair fringe surrounding the central glabrous area (Figure 408). The acarinarium of L. paraforbesii is not so distinctive (Figure 409) but the density of the associated fringe hairs and their sharply delimited central border will separate paraforbesii from similar species, e.g., L. trizonatum (Figure 693) and L. colatum (Figure 351). Females of the forbesii group can also be distinguished from the similar trizonatum females by their generally shorter heads (Figures 410, 425, 434, length/width ratio averages are 0.89, 0.90 and 0.92 for each species, n = 20 for each; compare with trizonatum females, Figures 670, 683, where averages range from 0.93 to 1.02).

The yellow tarsi and flat clypeal surface will separate the *forbesii* group males from those of other *Lasioglossum* species except for *L. chan-*

nelense and L. mellipes (both of which actually have yellowish orange tarsi). The latter species occur outside the range of the forbesii group and have either erect lateral hair tufts or a median rosette of erect hairs on sternum V (Figures 325, 701, 702; vestiture on sternum V of forbesii males inconspicuous, without noticeable pattern, Figure 416). Other males with yellow tarsi have the clypeal surface rounded and differ from forbesii males in the following additional characters: L. fuscipenne males have the posterior half of sterna II-IV densely covered by short, adpressed hair patches (Figure 189); L. leucozonium males have a unique V-shaped hair patch on sternum V (Figure 204); L. lampronotum males have a conspicuously wider head (Figure 487, length/width ratio  $\bar{x} = 0.82$ ); L. titusi males have the mesoscu-

tum virtually impunctate and have much shorter heads (Figure 633, length/width ratio  $\bar{x} = 0.85$ , n = 15).

DISCUSSION.—Besides having an acarinarium on the first tergum of the females, the *forbesii* group species, which occur primarily in the eastern United States, are somewhat generalized in appearance and have been commonly confused with those of the *trizonatum* group, their counterpart in the western United States (see above diagnosis for distinguishing characters) and even *L. coriaceum*. Cockerell (1898c) states that he

examined a great number of coriaceus from Wash.[ington state], and various specimens from New Mexico and Illinois, considered to be forbesii; also an Illinois coriaceus from Mr. Robertson. The result of this study is that I believe all belong to one somewhat variable species.

Cockerell's study was superficial, and he was further hindered by examining misidentified L. coriaceum from Washington, which were undoubtedly specimens of the trizonatum group (L. coriaceum and species of the forbesii group are not found in Washington state). Cockerell's statement is nevertheless indicative of the confusion that has surrounded specimens of the trizonatum and forbesii species groups.

It has long been apparent that the original, inclusive concept of *L. forbesii* as one species included high levels of variability in head shape, mandible length in the males, and great differences in body size among other characters. Cockerell (1898c:51) says that

it is to be remarked, however, that Robertson's description of the metathoracic enclosure [dorsal propodeal surface] of forbesii, bearing irregular radiating rugae, which reach the posterior margin, will hardly apply to what I have ... regarded as that species ....

The development of the propodeal rugae and the structure of the posterior propodeal edge are features that are now known to vary between species of the *forbesii* group and Cockerell's comments foreshadowed this understanding. Upon examining the abdominal acarinarium of hundreds of specimens, it became apparent that three forms are actually involved, herein recog-

nized as species. Females of L. acuminatum have a very unique acarinarium, the glabrous area of which is arrow-shaped and pointed dorsally (Figure 407). The males of L. acuminatum have very elongate mandibles that nearly reach the opposing mandibular bases and very wide, angulate genae and as a result have been commonly misidentified as L. coriaceum. Males of the latter species have dark tarsi and a non-elevated anterior mesoscutal edge (tarsi yellow and mesoscutum elevated in all forbesii group males). The females of L. forbesii and L. paraforbesii differ in acarinarial shape, head length, propodeal structure, and overall body size as detailed in the following species treatments. The males of these two forms apparently differ in head shape but cannot be reliably separated at present (L. forbesii length/width ratio  $\bar{x} = 0.90$ , L. paraforbesii  $\bar{x} =$ 0.93, n = 20 for each).

As for the *trizonatum* complex, it should be emphasized that the present treatment of the *forbesii* group is only preliminary in nature. Much more information on variability is needed and the possibility of hybridization addressed. Most helpful would be biological studies in those areas where the different forms are known to be sympatric.

#### 18. Lasioglossum acuminatum, new species

FIGURES 15, 406-407, 410-424

TYPE MATERIAL.—The female holotype of *L. acuminatum* is deposited in the National Museum of Natural History, Smithsonian Institution. The specimen is missing the left hind leg beyond the coxa but is otherwise in excellent condition. It is labeled

NEW HAMPSHIRE: Sullivan Co.[unty], Lempster, 23-VI [June]-1976 FC&BJ Thompson/HOLOTYPE Lasioglossum acuminatum R.J. McGinley [red label].

Ninety-eight paratypes (779, 218) listed in the "Specimens Examined" section are designated.

ETYMOLOGY.—The specific epithet is derived from the Latin *acumin* (a point), alluding to the

uniquely pointed, arrow-shaped acarinarium on the anterior surface of tergum I of the females.

DISTRIBUTION (Figure 406).—Lasioglossum acuminatum is primarily found in Canada and northern United States, from New Brunswick south to Pennsylvania and West Virginia, west through Michigan and Minnesota to central Alberta.

DIAGNOSIS.—The females of L. acuminatum can be distinguished from those of all other Lasioglossum species by the shape of the acarinarium on the anterior surface of tergum I, which is uniquely pointed and arrow-shaped (Figure 407). Other useful characters are the slightly elevated lateral rims on the posterior margin of the dorsal propodeal surface (Figure 414, characteristic of other forbesii group females) and the only moderately elongate head (Figure 410, length/width ratio  $\bar{x} = 0.90$ , n = 20).

Lasioglossum acuminatum males have the yellow tarsi typical of other forbesii group males but have extremely elongate mandibles that nearly reach the opposing mandibular bases (Figure 411), very broad, moderately angulate genae that are slightly wider than the width of the compound eye as seen in lateral view and elongate hairs on sternum IV that are subequal in length to those on sternum III as seen in lateral view (Figure 418). Lasioglossum forbesii and L. paraforbesii males have shorter mandibles that at most reach only slightly beyond the opposing clypeal angles (Figures 426, 435) and shorter hairs on sternum IV than on sternum III (Figure 417). The gena of L. forbesii males is always narrower than the width of the eye as seen in lateral view, whereas that of L. paraforbesii is variable, in some cases subequal in width to the eye.

DESCRIPTION.—FEMALE: (1) Length 8.0–10.3 mm ( $\bar{x} = 9.2$ , n = 20); (2) wing length 2.6–2.9 mm ( $\bar{x} = 2.8$ , n = 20); (3) abdominal width 2.7–3.2 mm ( $\bar{x} = 3.0$ , n = 20).

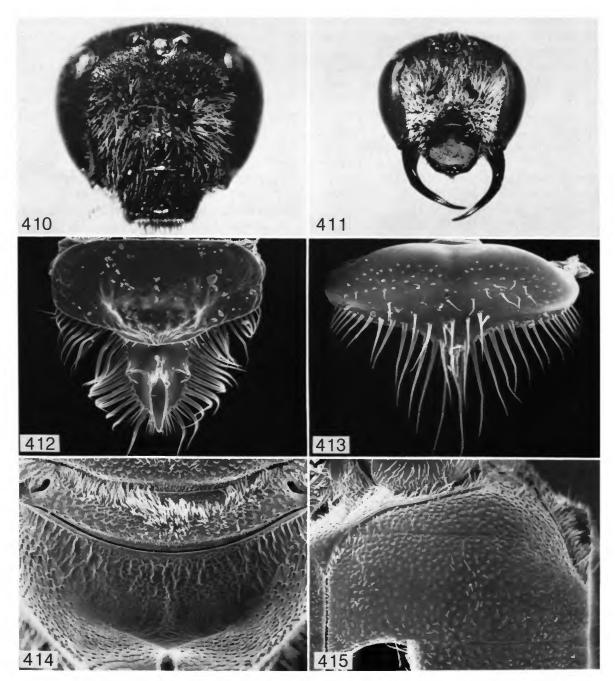

Structure: (4) Head moderately elongate (Figure 410, length/width ratio 0.85–1.0,  $\bar{x} = 0.91$ , n = 20). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.91 of its length below lower

margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 412; (27) distal keel moderately broad as seen in frontal view, slightly widest basally; (28) distal lateral projections somewhat moderately well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.79 the length of scutellum and about 1.5 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined laterally, evident medially as a V-shaped elevation with distinct lateral rims, fading towards mesonotum; (44) lateral carinae extending at most half the length of posterior surface. (45) Tibial spur as in Figure 15.

(46) Lateral edge of metasomal tergum II weakly sinuate, nearly straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area weakly granulate, (51) punctation nearly uniform, punctures separated by their width laterally, slightly less dense centrally. (53) Clypeus granulate along basal edge; (54) punctures separated by their width or slightly less, apicolateral areas virtually impunctate. (56) Mesoscutum dull; (57) punctation as in Figure 415, punctures separated by their width or less laterally and anteriorly, less dense centrally, punctures 1-4 times their width apart. (58) Scutellum with conspicuous impunctate areas adjacent to median line. (63) Dorsal surface of propodeum (Figure 414) variable in sculpture, completely to incompletely ruguloso-striate; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense,

FIGURES 410-415.—Lasioglossum acuminatum: 410, female head; 411, male head; 412, female labrum; 413, male labrum; 414, female propodeum; 415, female mesoscutum.

punctures slightly less than their width apart.

Coloration: (71) Wing membrane pale yellow

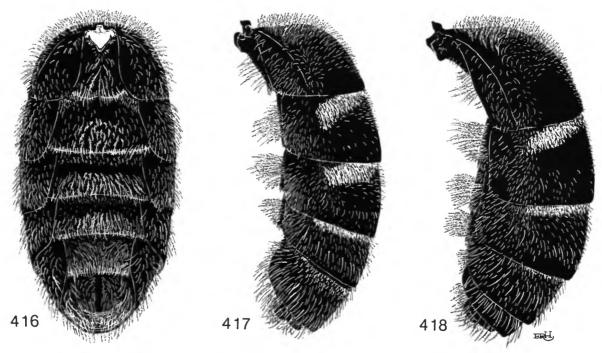

Coloration: (71) Wing membrane pale yellowish brown.

Vestiture: (74) Pubescence of head yellowish white. (75) Pubescence of thorax yellowish white; (76) mesoscutal hairs moderately sparse and plumose. (77) Hind tibial hairs concolorous, yellowish brown. (75) Anterior hairs of metasomal tergum I pale yellowish brown, (77) basal hair bands of terga II–IV white. (80) Acarinarium present (Figure 407), a relatively small, arrowhead-shaped, glabrous area surrounded laterally by elongate fringe hairs, dorsal opening of acarinarium very narrow, width of opening approximately one-half the width of lateral fringe hairs as seen in dorsal view; unlike most species, each side of tergum I with conspicuous bald areas posteriad of acarinarial fringe hairs.

MALE: Similar to female except as follows: (1) length 7.2–8.8 mm ( $\bar{x}=8.2$ , n=20); (2) wing length 2.1–2.5 mm ( $\bar{x}=2.3$ , n=20); (3) abdom-

inal width 1.8-2.3 mm ( $\bar{x} = 2.1$ , n = 20). (4) Head as in Figure 411 (length/width ratio 0.91-1.0,  $\bar{x} = 0.95$ , n = 20). (5) Gena slightly wider than eye, (6) strongly produced posteriorly. (10) Clypeal surface conspicuously flattened dorsally, shallowly depressed ventrally. Labrum as in Figure 413; (24) distal process developed as a moderately elongate, acute projection; (25) basal area depressed medially; (26) basal lateral depressions absent. (30) Mandible extremely elongate, reaching just short of opposing mandibular base. (53) Clypeus polished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum pale yellowish orange ventrally, contrasting with dark dorsum. (72) Tarsi yellow to yellowish orange.

Vestiture: Sternal vestiture as in Figure 418; (82) hairs on sternum IV erect, elongate medially, becoming shorter laterally (in lateral view, hairs of sternum IV subequal in length to those

FIGURES 416-418.—Lasioglossum forbesii group, male sternal vestiture: 416, L. forbesii abdomen, ventral view; 417, same, lateral view; 418, L. acuminatum abdomen, ventral view.

of sternum III, Figure 418; hairs of sternum IV relatively shorter in *L. forbesii* and *L. paraforbesii*); (83) sternum V without noticeable erect hairs or posterior hair lobes.

Terminalia: Sterna VII-VIII as in Figure 423; (85) sternum VIII with elongate, slender median process, broader apically than along stem. Genitalia as in Figures 419-422; (86) gonobase moderately elongate; (87) gonostylus broad, moderately elongate, narrowly rounded apically; (89) retrorse membranous lobe extremely slender; (90) volsella with very prominent lateral lobe.

FLIGHT RECORDS (Figure 424).—Females of L. acuminatum have been collected from April through October, with most records from June (50%). Males have been collected primarily in August and September, but one was taken in June (Barnstable County, Massachusetts) and six in late July.

FLOWER RECORDS.—Females (54): Ericaceae 46%; Rosaceae 17%; Compositae 11%. Males (49): Compositae 94%. Total: 103 in 13 families, 17 genera as follows:

Acer 1(1)\$\foats, Asclepias 2&\tilde{c}; Apocynum 1\foats, \*Brassica 1(1)\$\foats, Chamaedaphne 1\foats, Clethra 1&\tilde{c}; \*Lysimachia 1(1)\$\foats, Melilotus 1\foats, Rhododendron 3\foats, Prunus 1\foats, Pyrus 2\foats, \*Rosa 3(3)\$\foats, \*Rubus 6(2)\$\foats, \*Salix 4(1)\$\foats, \*Solidago 6(6)\$\foats, 46\tilde{c}; Vaccinium 21\$\foats, Viburnum 2\foats.

#### 19. Lasioglossum forbesii (Robertson)

FIGURES 406, 408, 425-433

Halictus Forbesii Robertson, 1890:315 [female, male].
Halictus forbesii.—Robertson, 1894 [emendation, flower records].—Cockerell, 1897:163 [flower and locality records]; 1898c:51 [taxonomic notes]; 1906:294 [locality record].—Graenicher, 1907 [flower records]; 1909 [flower records].—Cresson, 1928:60 [lectotype designation].

Lasioglossum forbesii.—Robertson, 1902:247 [key].—Michener, 1951:1106 [Nearctic catalog].—Evans, 1955:47 [predator, Philanthus sanbornii Cresson].—Mitchell, 1960:342 [redescription, key].—Knerer and Atwood, 1962:163 [nest, locality and flower records]; 1967:104 [conopid parasitoid].—Hurd, 1979:1957 [Nearctic catalog].

Curtisapis forbesii.—Robertson, 1918:91 [taxonomic notes]; 1929 [flower records].

Halictus forbesi.—Michener, 1951:1106.—Hurd, 1979: 1957 [lapsus calami].

Type Material.—The female lectotype of *Halictus forbesii*, designated by E.T. Cresson (1928), is deposited in the Academy of Natural Sciences at Philadelphia. The specimen is in ex-

cellent condition and is labeled

Robertson S.[outhern] Illinois/LectoTYPE 4257 [red label]/Halictus Forbesii Rob.[ertson] [handwritten].

I have not examined the other three females and two males from Robertson's original series; they are presumably also in Philadelphia.

DISTRIBUTION (Figure 406).—Although Lasioglossum forbesii is partly sympatric with L. acuminatum and L. paraforbesii it has the most southern distribution among species of the forbesii group. It is found from New York to Wisconsin and south to Oklahoma, Arkansas, and North Carolina.

DIAGNOSIS.—The hair fringe that surrounds the glabrous central area of the acarinarium on the anterior surface of tergum I is distinctively formed in L. forbesii. The elongate fringe hairs extend laterally on the tergal surface and form an extensive and thick hair patch with a distinctly transverse dorsal margin (Figure 408). The dorsal opening of the acarinarial hair fringe is extremely narrow, much more so than that of L. paraforbesii (Figure 409). The acarinarium of L. acuminatum, the other species in the forbesii group, is uniquely arrow-shaped (Figure 407). Other characters helpful in recognizing L. forbesii are the short head (Figure 425, length/width ratio  $\bar{x} = 0.89$ , n = 20; head longer in L. paraforbesii, Figure 434,  $\bar{x} = 0.92$ , n = 20) and the sharply-edged, posterolateral edges of the dorsal propodeal surface (this was mentioned in Robertson's original description).

Among forbesii group males (see above diagnosis of the forbesii group) the males of L. forbesii cannot reliably be separated from those of L. paraforbesii. Lasioglossum forbesii males have wider heads than those of the latter species (Figure 426, length/width ratio  $\bar{\mathbf{x}}=0.90,\,\mathbf{n}=20;$  compare with Figure 435,  $\bar{\mathbf{x}}=0.93,\,\mathbf{n}=20)$  but this character is at best difficult to work with. The extremely elongate mandibles of L. acuminatum males (Figure 411) will differentiate them from the above species.

DESCRIPTION.—FEMALE: (1) Length 7.0–9.4 mm ( $\bar{x} = 8.5$ , n = 20); (2) wing length 2.1–2.8

mm ( $\bar{x} = 2.5$ , n = 20); (3) abdominal width 2.4–3.1 mm ( $\bar{x} = 2.7$ , n = 20).

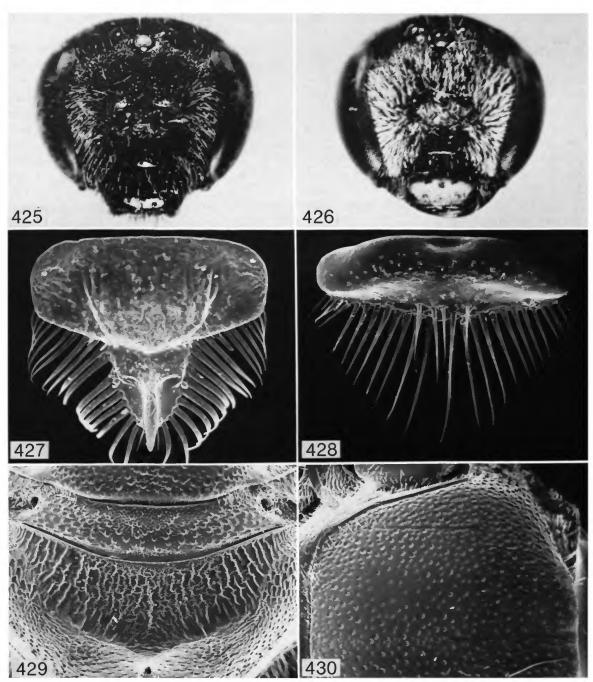

Structure: (4) Head short (Figure 425; length/width ratio 0.83-0.96,  $\bar{x}=0.89$ , n=20). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.64 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 427; (27) distal keel moderately narrow as seen in frontal view, lateral edges slightly bowed; (28) distal lateral projections weakly developed, rounded; (29) some fimbrial setae bluntly rounded.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.82 the length of scutellum and about 1.6 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle moderately well defined, evident medially as a V-shaped elevation with sharply-edged lateral rims, fading towards metanotum; (44) lateral carinae extending at most half the length of posterior surface. (45) Tibial spur similar to Figure 46.

(46) Lateral edge of metasomal tergum II moderately sinuate.

Sculpture: (47) Face shiny, (48) punctures moderately dense below ocelli, separated by at most their width, becoming less dense near antennae. (51) Supraclypeal area weakly granulate, (51) uniformly punctate, punctures separated by 1–2 times their width. (53) Clypeus polished; (54) punctures separated by their width basally, becoming less dense apically and apicolaterally. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 430, punctures separated by their width or less laterally and anteriorly, less dense centrally, punctures 1–4 times their width apart.

NUMBER 429

FIGURES 425-430.—Lasioglossum forbesii: 425, female head; 426, male head; 427, female labrum; 428, male labrum; 429, female propodeum; 430, female mesoscutum.

(58) Scutellum very sparsely punctate adjacent to median line, punctures 2-3 times their width apart. (63) Dorsal surface of propodeum (Figure 429) ruguloso-striate laterally, rugulose medially; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane pale yellowish brown.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately sparse and plumose. (77) Hind tibial hairs concolorous, yellowish brown. (78) Anterior hairs of metasomal tergum I and (76) basal hair bands of terga II–IV white. (80) Acarinarium present (Figure 408), a very small circular, glabrous area surrounded laterally and dorsally by elongate fringe hairs, dorsal fringe hairs forming a straight-edged acarinarial border; opening of acarinarium extremely narrow, width of opening approximately one-third the width of lateral fringe hairs as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 6.7-8.6 mm ( $\bar{x} = 7.5$ , n = 20); (2) wing length 1.9-2.3 mm ( $\bar{x} = 2.0$ , n = 20); (3) abdominal width 1.7-2.1 mm ( $\bar{x} = 1.9$ , n = 20). (4) Head as in Figure 426 (length/width ratio 0.85-0.95,  $\hat{x} = 0.88$ , n = 20). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 428; (24) distal process weakly developed, slightly projecting but not acutely pointed as in L. acuminatum and L. paraforbesii; (25) basal area depressed medially; (26) basal lateral depressions absent. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present (Figure 426). (69) Flagellum pale vellowish orange ventrally, contrasting with dark dorsum. (72) Tarsi yellow to yellowish orange.

Vestiture: Sternal vestiture as in Figures 416, 417; (82) hairs on sternum IV erect, elongate, becoming shorter laterally; (83) sternum V with

some inconspicuous erect hairs but without noticeable hair patterns or lobes.

Terminalia: Sterna VII-VIII as in Figure 431; (85) sternum VIII with elongate, slender median process, slightly broader apically than along stem. Genitalia similar to Figures 419–422; (86) gonobase moderately elongate; (87) gonostylus elongate, moderately slender, tapering to acute apex (Figure 432, more slender than that of L. acuminatum); (89) retrorse membranous lobe extremely slender; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS (Figure 433).—Females of L. forbesii have been collected from late March

FIGURES 431, 432.—Lasioglossum forbesii, male: 431, sterna VII-VIII; 432, gonostylus.

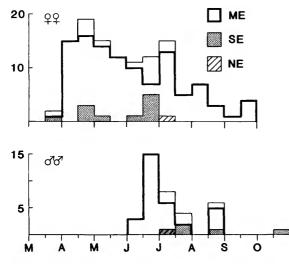

FIGURE 433.—Lasioglossum forbesii flight records (outer line = total).

(one female from southern Illinois and the other from Raleigh, North Carolina) through September, with a peak in late April. Males have been taken from June to August, with one record from late October (Black Mountains, North Carolina).

FLOWER RECORDS.—Females (45): Rosaceae 29%; Leguminosae 16%; Salicaceae 13%. Males (9): Leguminosae 50%. Total: 54 in 14 families, 20 genera as follows:

\*Amorpha 3(1)\$; Apocynum 18; Ceanothus 1\$, 2\$; Cercis 1\$; Claytonia 2\$; Galax 1\$; Houstonia 1\$; Hydrangea 1\$; Koellia 1\$; \*Melilotus 6(1)\$, 4\$; \*Prunus 4(2)\$; Rhamnus 3\$; \*Rhus 4(3)\$; \*Rubus 7(7)\$; Salix 6\$; \*Senecio 1(1)\$; Spirea 2\$; Taraxacum 1\$; Thaspium 1\$; Vitex 1\$.

### 20. Lasioglossum paraforbesii, new species

FIGURES 46, 406, 434-442

TYPE MATERIAL.—The female holotype of *L. paraforbesii* is deposited in the National Museum of Natural History, Smithsonian Institution. It is in excellent condition and is labeled

SOUTH DAKOTA Hardy W.[ork] C.[enter] T3N,R1E,S30 [extreme southwest corner of Lawrence County, southwest of Cheyenne Crossing on Route 85] 2-July 1965 R.W. Hodges/HOLOTYPE Lasioglossum paraforbesii R.J. Mc-Ginley [red label].

One hundred paratypes (809, 208) listed in the "Specimens Examined" section are designated.

DISTRIBUTION (Figure 406).—Lasioglossum paraforbesii is the most common and widespread species in the forbesii group and one of the commonest species throughout much of the eastern and central United States. It is found from New Brunswick to Alberta and Idaho and south to central New Mexico, Nebraska, Illinois, Ohio, and northern Virginia.

DIAGNOSIS.—Among species of the forbesii group (see introductory diagnosis to the group) the females of L. paraforbesii can be distinguished by the structure of the acarinarium on the anterior surface of tergum I (Figure 409). The glabrous central area of the acarinarium is circular, not arrow-shaped as is that of L. acuminatum (Figure 407), and the hair fringe surrounding the glabrous area has a wide dorsal opening, the width of which is nearly subequal to that of the lateral hair fringe as seen from above (this opening is extremely narrow in L. forbesii, Figure 408). Females of L. paraforbesii lack the sharply

edged posterolateral margins of the dorsal propodeal surface typical of *L. forbesii* and have longer heads than the latter species (Figure 434, length/width ratio  $\bar{x}=0.92, n=20$ ; compare with Figure 425,  $\bar{x}=0.89, n=20$ ).

The males of *L. paraforbesii* cannot be reliably separated from those of *L. forbesii* (see introductory diagnosis for the species group and the "Diagnosis" section for *L. forbesii*).

DESCRIPTION.—FEMALE: (1) Length 7.2–10.4 mm ( $\bar{x} = 9.1$ , n = 20); (2) wing length 2.3–2.9 mm ( $\bar{x} = 2.6$ , n = 20); (3) abdominal width 2.3–3.2 mm ( $\bar{x} = 2.9$ , n = 20).

Structure: (4) Head moderately short to moderately elongate (Figure 434; length/width ratio 0.82-0.96,  $\bar{x} = 0.92$ , n = 20). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.74 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 436; (27) distal keel moderately broad as seen in frontal view, lateral edges evenly bowed; (28) distal lateral projections somewhat weakly developed, rounded; (29) some fimbrial setae bluntly rounded.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.73 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined laterally, evident medially as a V-shaped elevation with low lateral rims; (44) lateral carinae extending less than half the length of posterior surface. (45) Tibial spur as in Figure 46.

(46) Lateral edge of metasomal tergum II weakly sinuate, nearly straight.

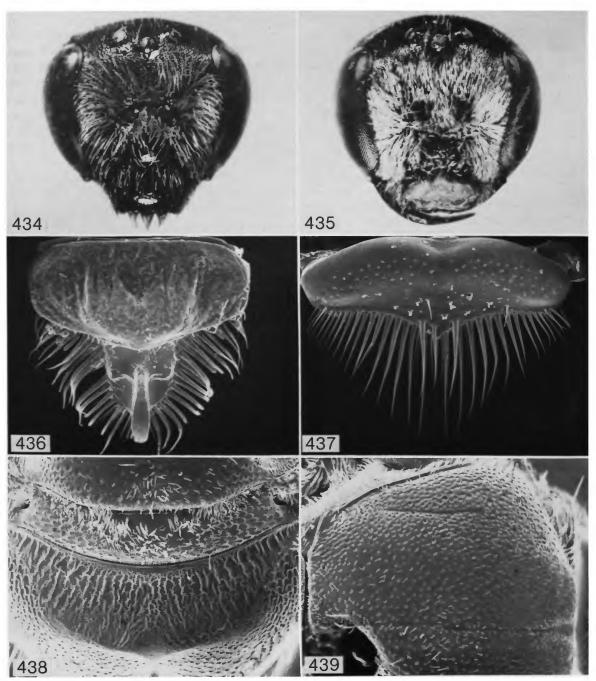

Sculpture: (47) Face shiny, (48) densely punc-

tate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area polished, (51) punctures separated by 1-2 times their width laterally, becoming sparse centrally. (53) Clypeus polished; (54) punctures separated by their width basally, apical one-third virtually impunctate. (56) Mesoscutum shiny; (57) punctation as in Figure 439, punctures separated by their width or less laterally and anteriorly, less dense centrally, punctures 1-3 times their width apart. (58) Scutellum very sparsely punctate adjacent to median line with conspicuous impunctate areas. (63) Dorsal surface of propodeum (Figure 438) ruguloso-striate over basal two-thirds, posterior one-third smooth or obscurely striolate; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane pale yellowish brown.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white to pale yellowish brown, white on pronotal lateral angle, pronotal lobe and metanotum; (76) mesoscutal hairs moderately sparse and plumose. (77) Hind tibial hairs concolorous, yellowish brown. (78) Anterior hairs of metasomal tergum I white to yellowish white, (79) basal hair bands of terga II–IV white. (80) Acarinarium present (Figure 409), a relatively small, circular, glabrous area surrounded laterally by elongate fringe hairs, dorsal opening of acarinarium moderately wide, width of opening slightly exceeded by width of lateral hair fringe as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 6.9–9.0 mm ( $\bar{x}=8.0$ , n=20); (2) wing length 1.8–2.3 mm ( $\bar{x}=2.6$ , n=20); (3) abdominal width 1.8–2.3 mm ( $\bar{x}=2.1$ , n=20). (4) Head as in Figure 435 (length/width ratio 0.88–0.96,  $\bar{x}=0.93$ , n=20). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (10) Clypeal surface nearly flat, only faintly depressed ventrally. Labrum as in Figure 437; (24) distal process weakly developed as a short, acute projection; (25) basal area depressed

FIGURES 434-439.—Lasioglossum paraforbesii: 434, female head; 435, male head; 436, female labrum; 437, male labrum; 438, female propodeum; 439, female mesoscutum.

medially; (26) basal lateral depressions absent. (30) Mandible moderately elongate, reaching slightly beyond opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present (Figure 435). (69) Flagellum light brown ventrally, contrasting with dark dorsum. (72) Tarsi yellow to yellowish orange.

Vestiture: Sternal vestiture as in Figures 416, 417; (82) hairs on sternum IV erect, elongate, becoming shorter laterally; (83) sternum V with some inconspicuous erect hairs but without noticeable hair patterns or lobes.

Terminalia: Sterna VII-VIII as in Figure 440; (85) sternum VIII with moderately elongate, parallel-sided median process. Genitalia as

440

FIGURES 440, 441.—Lasioglossum paraforbesii, male: 440, sterna VII-VIII; 441, gonostylus.

in Figure 441; (86) gonobase moderately elongate (same as *L. forbesii* for other characters).

FLIGHT RECORDS (Figure 442).—Lasioglossum paraforbesii females have been collected from April through October. Of these records, 63% come from May and June, with a definite peak in May for specimens from the middle-eastern and southwestern regions. Females from the northwestern region peak in late June. Males have been taken from June through October, with 66% of the records coming from July and August.

FLOWER RECORDS.—Females (372): Rosaceae 46%; Compositae 13%. Males (42): Compositae

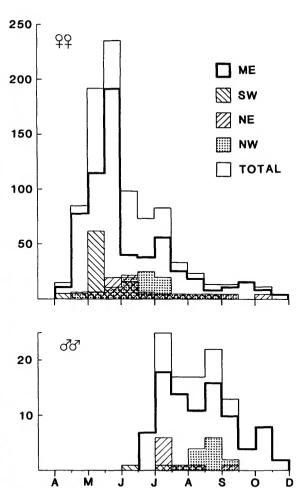

FIGURE 442.—Lasioglossum paraforbesii flight records.

40%; Leguminosae 38%. Total: 414 in 24 families, 65 genera as follows:

### 21. Lasioglossum fuscipenne (Smith)

FIGURES 33, 443-456

Halictus fuscipennis Smith, 1853:67 [female, male].—Dalla Torre, 1896:62 [World catalog].

Lasioglossum fuscipenne.—Robertson, 1902:34 [key].—Michener, 1951:1106 [Nearctic catalog].—Mitchell, 1960:343 [redescription, key].—Knerer and Atwood, 1962:163 [locality and flower records].—Hurd, 1979:1957 [Nearctic catalog].—Duffield et al., 1981:323 [Dufour's gland chemistry].

Halictus capitulatus Vachal, 1904:472 [female].—Cockerell, 1905a:90 [key].—Mitchell, 1960 [synonymy].

Curtisapis fuscipennis.—Robertson, 1918:91.—Reinhard, 1924:371 [predator, *Philanthus gibbosus*].—Robertson, 1929 [flower records].

TYPE MATERIAL.—In his original description of Halictus fuscipennis, Smith described the fe-

male and male but his only reference to the type series was "Hab. St. John's Bluff, East Florida. (Coll. E. Doubleday, Esq.)." The lectotype female, herein designated, is associated with the above data and is labeled "Type" (handwritten by Smith?). Its full label data are

Type H.T. [circular label with orange-red border]/B.M. TYPE HYM. 14.a.1005/B.M. TYPE HYM. Halictus fuscipennis Smith 1853/fuscipenne Sm.[ith] Type [handwritten by Smith?]/E. Doubleday. St. John's Bluff, E.[ast] Florida./ LECTOTYPE Halictus fuscipennis Smith des.[ignated by] McGinley [red label].

The lectotype, in the British Museum (Natural History), is missing the left antenna and the hind left tarsus but is otherwise in fair condition.

The female holotype of *Halictus capitulatus*, in the Paris Museum (MNHNP), is labeled

Teness.[Tennessee]/Museum Paris, coll. O. Sichel 1867/ Holotype [handwritten on red label]/capitulatus Vach.[al] ¶ [handwritten]/Halictus capitulatus Vach.[al] [handwritten].

During shipment in August 1983, the abdomen beyond the first metasomal segment broke off. This was apparently due to weakening of the area by old dermestid damage as evidenced by a small circular hole on the right side of the abdomen. The abdomen was reglued to the specimen with PVA by McGinley. The specimen is also missing the last two tarsomeres of the middle left leg but is otherwise in good condition. Moure and Hurd (1986) have correctly noted that the holotype is labeled only from "Teness. [Tennessee]," whereas in the original description Vachal recorded the type from "Teness., Mex.[ico]"; the Mexican reference evidently the result of an error in transcription.

DISTRIBUTION (Figure 443).—Lasioglossum fuscipenne is presently known to occur from Massachusetts through southern Florida and west to Michigan, eastern Kansas, and eastern Oklahoma. Hurd (1979) records this species from Nova Scotia to Ontario, south to Texas and Florida. Although I have not seen specimens from Texas and Ontario, their occurrence there is possible; the northern records to Nova Scotia are undoubtedly incorrect.

DIAGNOSIS.—The females of Lasioglossum fuscipenne can be distinguished from all other New World Lasioglossum by their distinctive dorsal propodeal surface (Figure 448), which is sharply truncated posteriorly; the lateral rims of the propodeal triangle are low but distinct and enclose a ruguloso-striate to irregularly striate area that sharply contrasts with the smooth propodeal surface outside the lateral rims. Additional helpful characters are the sharply pointed pronotal lateral angle, which forms a right angle (Figure 449), the relatively sparse mesoscutal punctation with most punctures separated by a distance greater than their width (Figure 449), and the lack of a first metasomal acarinarium.

Males of Lasioglossum fuscipenne are unique in having the posterior half of metasomal sterna II—IV densely covered by short, conspicuous hair patches (Figure 189). Unlike other Lasioglossum from the eastern United States except L. leucozonium and L. zonulum, the clypeus is rounded, not conspicuously flattened. The head is noticeably narrowed below with the eyes converging ventrally (Figure 445, similar to head of L. leucozonium, Figure 493). Both L. leucozonium and L. zonulum males differ greatly from those of L. fuscipenne in their sternal vestiture (compare Figures 189, 204, 205). As in the female, the pronotal lateral angle of the male L. fuscipenne is sharply produced.

DESCRIPTION.—FEMALE: (1) Length 8.2–10.1 mm ( $\bar{x} = 9.2$ , n = 15); (2) wing length 2.7–3.1 mm ( $\bar{x} = 2.9$ , n = 15); (3) abdominal width 2.7–3.2 mm ( $\bar{x} = 3.0$ , n = 15).

Structure: (4) Head moderately elongate (Figure 444; length/width ratio 0.88-0.96,  $\bar{x}=0.92$ , n=15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.70 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli slightly exceeding distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 446; (27) distal keel narrow in frontal view, lateral edges slightly bowed; (28) distal

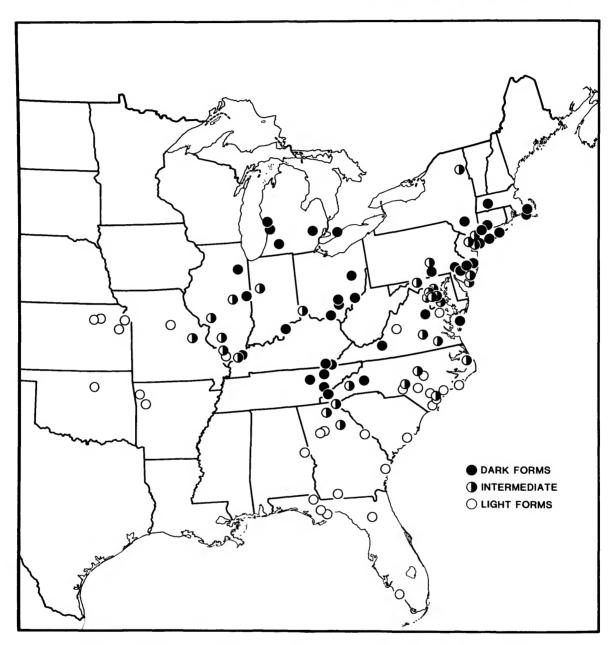

FIGURE 443.—Distribution of *Lasioglossum fuscipenne* showing distribution of specimens with dark legs (dark forms), specimens with yellowish orange middle and hind tibiae and tarsi (light forms), and localities where intermediate forms or a mixture of dark and light forms occur (see "Remarks" section).

lateral projections absent; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle forming well-produced right angle; (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (35) Mesoscutal lip moderately bilobed, (36) strongly elevated from pronotum. (40) Dorsal surface of propodeum about 0.88 the length of scutellum and about 1.5 times the length of metanotum, (41) not depressed centrally, (42) posterior margin sharply truncated; (43) propodeal triangle weakly to moderately well defined, evident medially as a low Vshaped elevation with low but distinct lateral rims extending towards metanotum; (44) lateral carinae encircling posterior surface of propodeum, interrupted medially by V-shaped elevation. (45) Tibial spur as in Figure 33.

(46) Lateral edge of metasomal tergum II very weakly sinuate, nearly straight posteriorly.

Sculpture: (47) Face moderately shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area extremely granulate, (51) uniformly punctate, punctures separated by 1-3 times their width. (53) Clypeus granulate; (54) punctation nearly uniform, punctures separated by their width, becoming larger apically. (56) Mesoscutum moderately shiny, noticeably but finely patterned; (57) punctation nearly uniform throughout (Figure 449), punctures usually 2 times their width apart. (58) Scutellum nearly uniformly punctate, punctures less dense than those of mesoscutum, 1-4 times their width apart. (63) Dorsal surface of propodeum (Figure 448) ruguloso-striate, striae becoming more irregular medially, not reaching posterior margin; (64) surface alveolated. (65) Metasomal tergum I moderately dull, obscurely granulate; (66) punctation very fine, obscure, punctures separated by 1-3 times their width.

Coloration: (71) Wing membrane with clinal variation in pigmenation, correlated with leg color: southern forms with pale yellowish orange legs have conspicuously infuscated wings, especially anteriorly in marginal cell to apex; north-

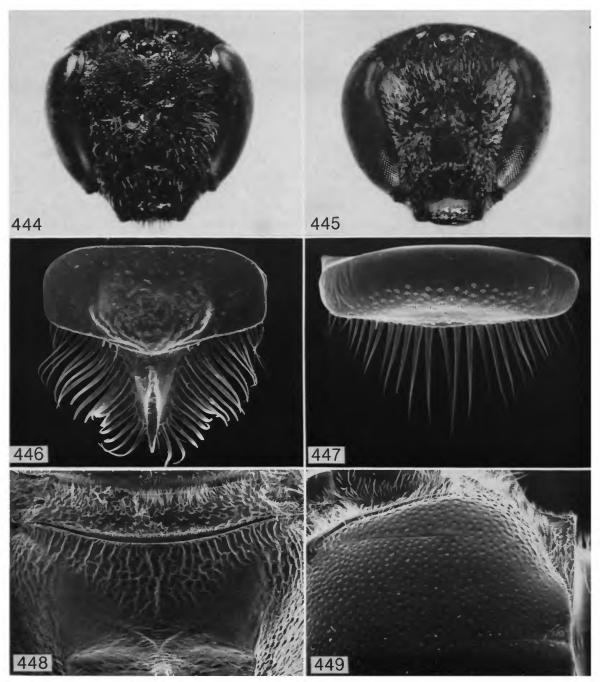

ern forms with dark legs have lightly infuscated wings (see "Remarks" section). (72) Unlike most species, legs show apparent clinal variation in pigmentation: southern and western forms with tibiae and tarsi of middle and hindlegs pale yellowish orange (see "Remarks" section).

Vestiture: (74) Pubescence of head pale yellowish brown to white. (75) Pubescence of thorax white to yellowish white; (76) mesoscutal hairs sparse, obscurely plumose. (77) Hind tibial hairs concolorous, yellowish brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 7.3–9.6 mm ( $\bar{x} = 8.1$ , n = 15); (2) wing length 2.2–2.5 mm ( $\bar{x} = 2.3$ , n = 15); (3) abdominal width 1.8-2.5 mm ( $\bar{x} = 2.0, n = 15$ ). (4) Head as in Figure 445 (length/width ratio 0.80-1.0,  $\bar{x} = 0.93$ , n = 15). (5) Gena conspicuously narrower than eye; (6) rounded, not produced posteriorly. (10) Clypeal surface broadly rounded, not flattened or depressed. Labrum as in Figure 447; (24) distal process virtually absent; (25) basal area rounded medially, not depressed; (26) basal lateral depressions absent. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate; (54) punctures well formed throughout, less dense on apical half, approximately 1-2 times their width apart. (68) Clypeal maculation present (Figure 445). (69) Flagellum brown ventrally, contrasting with dark dorsum. (72) Tarsi dark, concolorous with tibiae or tarsi yellowish orange, contrasting with dark tibiae (pale leg coloration occurs in the southern and western portions of the species distribution; see "Remarks" section).

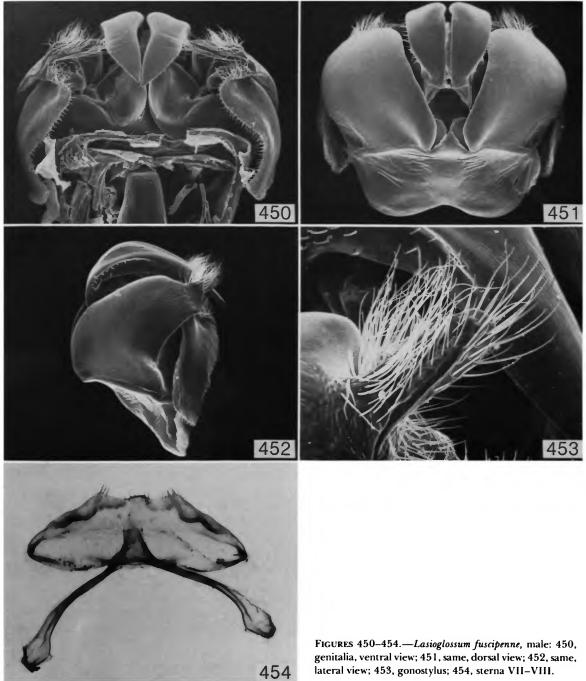

Vestiture: Sternal vestiture as in Figure 189; (82) sternum IV (as well as sterna II–III) with conspicuous patches of dense, adpressed hairs; (83) sternum V with less conspicuous, median rosette of adpressed hairs, posterior edge of sternum with moderately elongate lateral hair fringes.

Terminalia: Sterna VII-VIII as in Figure 454; (85) sternum VIII without median process.

FIGURES 444-449.—Lasioglossum fuscipenne: 444, female head; 445, male head; 446, female labrum; 447, male labrum; 448, female propodeum; 449, female mesoscutum.

NUMBER 429 155

Genitalia as in Figures 450–453; (86) gonobase moderately elongate; (87) gonostylus moderately elongate and broad, parallel-sided, apex broadly rounded; (89) retrorse membranous lobe moderately broad; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS (Figure 455).—Label data indicate that *L. fuscipenne* is possibly bivoltine in the southern portion of its range. In Arkansas, Florida, Georgia, North Carolina, and South Carolina males have been collected in March and April and then again from October through early December. Females in this area have only been collected from March to July but undoubtedly occur later in the season along with the males. Northern records suggest a univoltine pattern, with females most commonly collected in May and early June. Males in the mid-Atlantic region have been most commonly taken in early October.

FLOWER RECORDS.—95% of the floral records

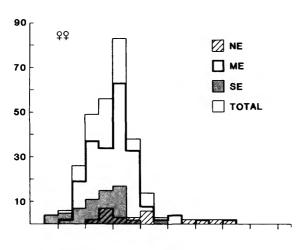

FIGURE 455.—Lasioglossum fuscipenne flight records.

for Lasioglossum fuscipenne males were from the Compositae. This is probably a result of the many late season records for this species during the abundance of Aster and Solidago blooms rather than due to any specificity on the part of the bees. Little can be said about female floral associations other than that they are most likely polylectic.

Summary: Females (74): Anacardiaceae 24%; Fagaceae 11%; Compositae 11%; Hydrophyllaceae 10%. Males (118): Compositae 95%. Total: 192 in 22 families, 34 genera as follows:

Alliaria 29; Apocynum 39; Aquilegia 19; Aruncus 19; Asclepias 19; Aster 368; Barbarea 39; Batodendron 19; Bidens 138; Carya 18; Castanea 89; Ceanothus 59; Chrysanthemum 39, 28; Erigeron 19; Euphorbia 19; Geranium 19; Hydrophyllum 79; Ilex 29; Krigia 19; \*Ligustrum 1(1)9; Linaria 19; Lobelia 19; Lyonia 18; Prunus 28; Pyrus 19; Rhus 179; Salix 39; 28; Senecio 39, 28; Solidago 588; Tephrosia 29; Vaccinium 19, 18; Viburnum 19; Vitis 19; Waldsteinia 19.

REMARKS.—As illustrated in the *L. fuscipenne* distribution map (Figure 443), specimens having entirely dark legs occur primarily in the northern portion of the species range. Forms having the tibiae and tarsi of the middle and hindlegs pale yellowish orange are found to the south and far west. Localities where females are intermediate in leg color or where both color forms are found are indicated on the map by half-darkened dots. An examination of the specimens from three intermediate localities also indicates a clinal trend in pigmentation (Figure 456). Unlike the females, where intermediacy in leg color is common, the legs of males are either dark or light.

## 22. Lasioglossum heterorhinum (Cockerell)

FIGURES 34, 457-471

Halictus heterorhinus Cockerell, 1930:6 [female].

Lasioglossum heterorhinum.—Michener, 1951:1106 [Nearctic catalog].—Hurd, 1979:1957 [Nearctic catalog].

TYPE MATERIAL.—The female holotype, in

the American Museum of Natural History, is labeled

Mesa Verde [Montezuma County], Colo. [rado] July 3-7, [19]'19 F4370F [?]/About 37°12' N.[orth] "[about] 108°29' W.[est]" [about] 7300 ft.[feet]/Halictus heterorhinus Ckll. [Cockerell] TYPE [handwritten by Cockerell]

The specimen is missing the right antenna and the tibia and tarsus of the hind left leg but otherwise is in excellent condition. No paratypes were designated by Cockerell.

DISTRIBUTION (Figure 457).—Lasioglossum heterorhinum is found through portions of the Rocky Mountain system and the Black Hills, south into Mexico. Many specimens are associated with elevation data that range from 4300 to 9000 feet. In the United States this species is now known from Arizona, Colorado, Nevada, New Mexico, South Dakota, and Utah. Two females in the Oregon State Collection were collected in Hidalgo, Mexico. They appear to be conspecific with the northern specimens, apparently differing only by their darker scopal hairs. Also appearing conspecific is one male collected in Veracruz (Utah State University). Future collecting in the mountainous areas of northern and central Mexico will probably produce more specimens of this species.

DIAGNOSIS.—Lasioglossum heterorhinum can be recognized by the following unique character combination: pronotal lateral carina complete, not interrupted by oblique sulcus (as in Figure 9); mesoscutum dull, granuloso-punctate on anterior half, punctures less dense and surface shiny on posterior half (Figure 463); acarinarium absent, elongate, dense hairs scattered over anterior surface of metasomal tergum I; head short (Figure 458, length/width ratio 0.76–0.92,  $\bar{x} = 0.86$ ); basal half of clypeus conspicuously granulate, contrasting with polished apical half; wing membranes pale yellowish brown.

In the United States, only two other species have a complete pronotal lateral carina, *L. lam-pronotum* and *L. channelense* (carina actually microscopically notched, Figure 100). The mesoscutum of *L. lampronotum* is very shiny throughout, not dull, granuloso-punctate on the anterior

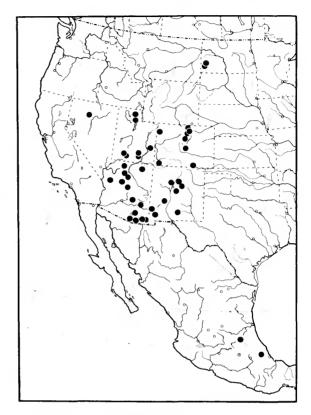

FIGURE 457.—Distribution of Lasioglossum heterorhinum.

half. Lasioglossum lampronotum also has a completely polished clypeus (not granulate basally), hyaline wing membranes (not pale yellowish brown), and pale yellowish orange hind legs (usually dark brown in L. heterorhinum). Lasioglossum channelense, known only from the Channel Islands of California, is easily differentiated by its relatively elongate head (Figure 319) and metasomal acarinarium (Figure 330). Lasioglossum rupticristum is very similar to and sympatric with L. heterorhinum but has an incomplete pronotal lateral carina, hyaline wings, and an entirely polished clypeus.

A number of Mexican Lasioglossum species have complete pronotal lateral carinae but differ from L. heterorhinum in details of mesoscutal or propodeal sculpture, or by having acarinaria or elongate heads. Lasioglossum argutum is the most similar Mexican species to L. heterorhinum but

can be recognized by its distinctive dorsal propodeal surface, which is highly polished and shiny on the posterior half.

The males of *L. heterorhinum* and *L. lampronotum* can be recognized by their broad heads (Figures 459, 487), complete pronotal lateral carina (as in Figure 9), and characteristic hair lobes on the posterior edge of sternum V (Figure 464; these lobes are more widely separated than those of *L. desertum*, Figure 387). *Lasioglossum heterorhinum* differs from *L. lampronotum* by having dark brown tarsi (yellowish white in *L. lampronotum*), and like the females, having the anterior portion of the mesoscutum granulosopunctate (punctures distinctly separated in *L. lampronotum*).

DESCRIPTION.—FEMALE: (1) Length 7.5–9.0 mm ( $\bar{x} = 8.5$ , n = 15); (2) wing length 2.4–2.8 mm ( $\bar{x} = 2.6$ , n = 15); (3) abdominal width 2.5–2.9 mm ( $\bar{x} = 2.7$ , n = 15).

Structure: (4) Head short (Figure 458; length/width ratio 0.76-0.92,  $\bar{x} = 0.86$ , n = 15). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.64 of its length below lower margin of eyes; (11) surface with obscure median longitudinal sulcation present in most specimens (weakly developed or obscured by punctures in some). (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 460; (27) distal keel moderately broad in frontal view, lateral edges bowed; (28) distal lateral projections weakly developed, rounded; (29) most fimbrial setae bluntly pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge complete, obscure oblique lateral sulcus reaching ridge but not distinctly interrupting it; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.78 the length of scutellum and about 1.3 times the length of metanotum, (41) very slightly depressed centrally, (42) posterior margin

broadly rounded; (43) propodeal triangle weakly defined, evident medially as a low V-shaped elevation with low lateral rims, fading towards metanotum; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 34.

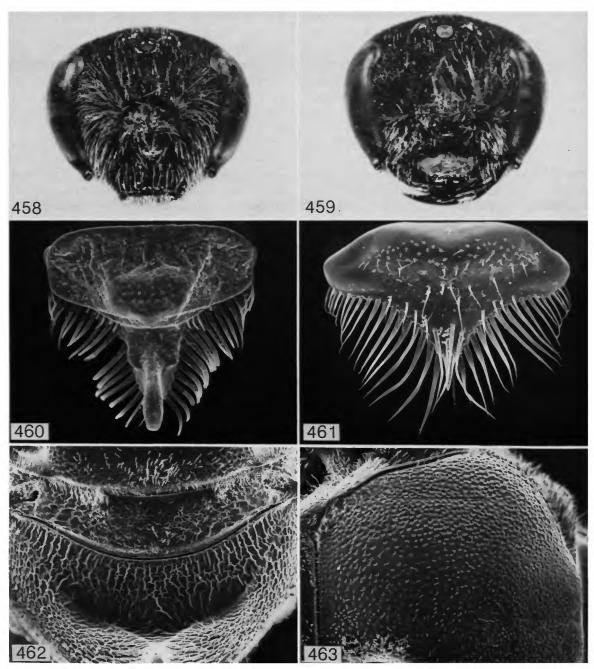

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face moderately shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) uniformly punctate, punctures separated by 1-3 times their width. (53) Clypeus strongly granulate basally, apical half polished; (54) punctation obscure, virtually absent apicolaterally. (56) Mesoscutum mostly shiny, dull anteriorly; (57) punctation as in Figure 463, punctures extremely dense laterally, contiguous, becoming granuloso-punctate anteriorly, relatively sparse centrally, punctures less dense anteriorly adjacent to median line, separated by their width. (58) Scutellum granuloso-punctate posteriorly, punctures less dense anteriorly adjacent to median line, separated by width. (63) Dorsal surface of propodeum (Figure 462) mostly rugulose, ruguloso-striolate on extreme lateral edges, striae and rugulae reaching posterior margin; (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration: (71) Wing membrane very pale yellowish brown.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hairs concolorous, pale yellowish brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 7.0–8.6 mm ( $\bar{x}=7.7$ , n=2); (2) wing length 2.1–2.6 mm ( $\bar{x}=2.4$ , n=15); (3) abdominal width 1.8–2.6 mm ( $\bar{x}=2.2$ , n=15). (4) Head as in Figure 459 (length/width ratio 0.77–

FIGURES 458-463.—Lasioglossum heterorhinum: 458, female head; 459, male head; 460, female labrum; 461, male labrum; 462, female propodeum; 463, female mesoscutum.

0.92,  $\bar{x} = 0.86$ , n = 15). (5) Gena conspicuously wider than eye; (6) strongly produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 461; (24) distal process developed as an elongate, acute projection; (25) basal area only moderately depressed medially; (26) basal lateral depressions well developed. (30) Mandible moderately elongate, reaching slightly beyond opposing clypeal angle. (53) Clypeus granulate along basal edge, apical two-thirds polished; (54) punctation somewhat uniform throughout, punctures over apical twothirds slightly less dense than basal punctures. (68) Clypeal maculation present (Figure 459). (69) Flagellum entirely dark or only slightly paler ventrally than on dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 464; (82) hairs on sternum IV moderately elongate, suberect; (83) sternum V with a median rosette of short hairs, posterior edge of sternum with broadly rounded and widely separated lateral hair lobes.

Terminalia: Sterna VII-VIII as in Figure

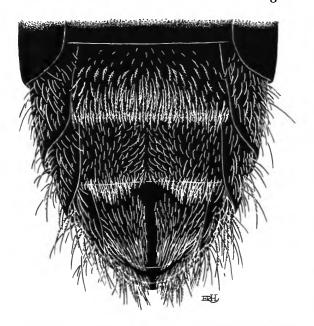

FIGURE 464.—Lasioglossum heterorhinum, male sternal vesti-

470; (85) sternum VIII with elongate, slender median process, process parallel-sided or with apex slightly broader than stem. Genitalia as in Figures 465–469; (86) gonobase moderately elongate; (87) gonostylus extremely broad and membranous basally, forming a basal collar as in Figure 468, abruptly tapering to a short, narrowly rounded apical portion (in some specimens the entire gonostylar area is highly convoluted and apparently distorted as in Figure 469); (89) retrorse membranous lobe very slender (unlike other species, except *L. lampronotum*, apex of gonocoxite near base of retrorse lobe conspicuously hairy); (90) volsella with prominent lateral lobe.

FLIGHT RECORDS (Figure 471).—Females of *L. heterorhinum* have been collected from March through October, with most records from late June. All of the March records are from Cochise Co., Arizona; the September and October records, also from Arizona, are from Cochise and Santa Cruz counties. Most male records are from April but range from February (Veracruz, Mexico) to June.

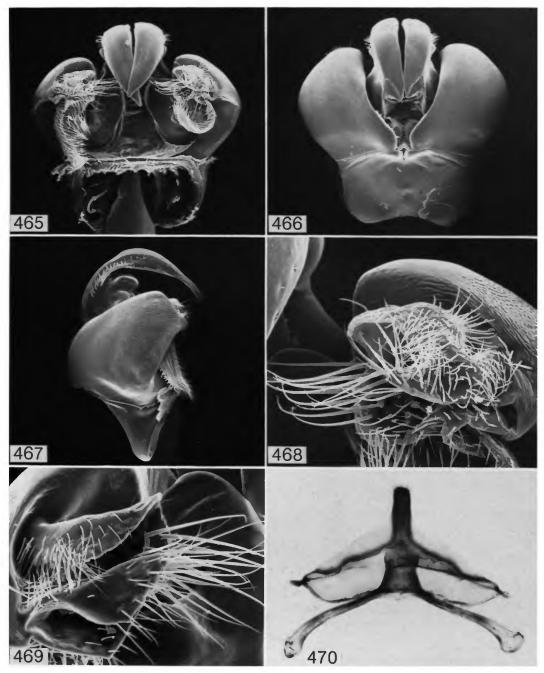

FLOWER RECORDS.—Females (53): Compositae 47%; Rosaceae 17%. Total: 53 in 13 families, 17 genera as follows:

\*Arctostaphylos 1(1)9; \*Asclepias 1(1)9; Atriplex 29; Berberis 39; Brassica 19; Ceanothus 19; \*Cercocarpus 1(1)9; \*Cimicifuga (1)9 (collecting pollen, O. Pellmyr, pers. comm.); Erigeron 279; Geranium 19; Pentstemon 39; \*Phacelia 1(1)9; \*Potentilla (1)9; Purshia 29; Ranunculus 29; \*Salix 3(2)9; Trifolium 29.

### 23. Lasioglossum jubatum (Vachal)

FIGURES 35, 472-483

Halictus jubatus Vachal, 1904:474 [female].—Cockerell, 1905a:90 [key].

Lasioglossum jubatum.—Moure and Hurd, 1986:62 [catalog].

TYPE MATERIAL.—The female holotype is labeled

Museum Paris Mexique, coll. O. Sichel 1867/Mex[ico] [illegible word, probably Sichel] [18]64 [handwritten]/Holotype [handwritten on red label]/jubatus Vach[al] [handwritten]/Halictus jubatus Vach.[al] [handwritten].

This specimen, in the Paris Museum (MNHNP), is missing the fifth tarsomere of the

left hind leg and some thoracic hairs are matted, but is otherwise in excellent condition. The small pin holes in both pleural walls indicate that the type was originally double-mounted and later repinned dorsoventrally.

DISTRIBUTION (Figure 472).—Lasioglossum jubatum is a wide-ranging species known from southeastern Arizona, scattered localities throughout Mexico south to Chiapas, Guatemala, and El Salvador. Twelve males are only tentatively associated with this species and are therefore mapped separately (see "Remarks" section). The localities herein reported from Cochise County, Arizona, are the first records of this species north of the Mexican border.

DIAGNOSIS.—The pale orange to golden hairs of the vertex, pronotum, mesoscutum, scutellum, and metanotum that sharply contrast with the white pubescence of the rest of the head, thorax, and abdomen will distinguish Lasioglossum jubatum from all other known New World Lasioglossum. Additional characters helpful in recognizing L. jubatum are the short head (Figure 473, length/width ratio 0.74-0.92,  $\bar{x}=0.84$ ), granuloso-punctate mesoscutum (Figure 477), and large acarinarium (Figure 478). The pronotal lateral ridge shows some variability in being complete (as in Figure 9) or obscurely notched.

The tentatively associated males can be distinguished from all other know *Lasioglossum* males by the elongate, rounded, and widely separated hair lobes on the posterior edge of sternum V (Figure 483). Other helpful characters are the short head, complete to virtually complete pronotal lateral ridge, and the conspicuous apicomedial depression of the clypeal surface.

DESCRIPTION.—FEMALE: (1) Length 7.8–10.0 mm ( $\bar{x} = 9.1$ , n = 15); (2) wing length 2.4–2.7 mm ( $\bar{x} = 2.6$ , n = 15); (3) abdominal width 2.6–3.1 mm ( $\bar{x} = 2.8$ , n = 15).

Structure: (4) Head short (Figure 473, length/width ratio 0.74-0.92,  $\bar{x} = 0.84$ , n = 15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.79 of its length below lower margin of eyes; (11) surface with narrow to broad

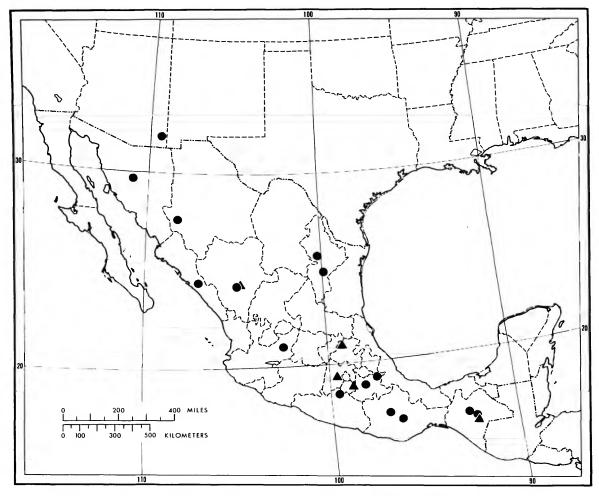

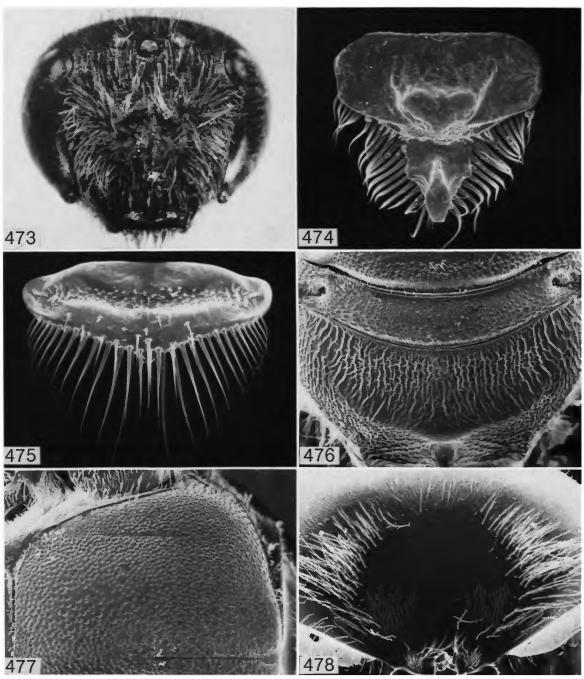

FIGURE 472.—Distribution of *Lasioglossum jubatum* females (circles) and tentatively associated males (triangles).

median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 474; (27) distal keel broad in frontal view, spoon-shaped; (28) distal lateral projections well developed, triangular, not sharply pointed; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, obscurely interrupted by oblique lateral sulcus to virtually complete; (34) lower portion of lateral ridge

sharply edged. (35) Mesoscutal lip very weakly bilobed, (33) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.83 the length of scutellum and about 1.4 times the length of metanotum, (41) depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle moderately well defined laterally, lateral rims absent, evident medially as a low V-shaped elevation; (44) lateral carinae very well developed but extending only slightly beyond midpoint of posterior surface. (45) Tibial spur as in Figure 35.

FIGURES 473-478.—Lasioglossum jubatum: 473, female head; 474, female labrum; 475, male labrum; 476, female propodeum; 477, female mesoscutum; 478, female acarinarium at base of tergum I.

(46) Lateral edge of metasomal tergum II weakly sinuate, nearly straight.

Sculpture: (47) Face moderately shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) punctures separated by their width laterally, becoming very sparse centrally. (53) Clypeus granulate basally, apical half polished; (54) punctures separated by less than their width basally, less dense and obscure medially to apex, apicolateral areas impunctate. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 477, granulosopunctate laterally and anteriorly, less dense centrally, punctures 1-3 times their width apart. (58) Scutellum with sparse, fine punctation adjacent to median line, punctures 1-3 times their width apart. (63) Dorsal surface of propodeum (Figure 476) ruguloso-striolate, striae reaching posterior margin; (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white near antennae and on genae, becoming golden on vertex. (75) Pubescence of thorax white on pleuron, propodeum, metathorax and pronotal lobes; deep golden to pale orange on pronotum, mesoscutum and scutellum; (76) mesoscutal hairs dense, conspicuously plumose. (77) Hind tibial hair color differentiated, hairs mostly white, dorsal hairs dark brown basally, brown distally to apex. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II-IV white. (80) Acarinarium present (Figure 478), a large circular, glabrous area surrounded laterally and dorsally by elongate fringe hairs, dorsal opening of acarinarium wide, width of opening slightly exceeding width of lateral hair fringe as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 7.1–8.8 mm ( $\bar{x} = 8.2$ , n = 10); (2) wing length 2.0–2.7 mm ( $\bar{x} = 2.3$ ); (3) abdominal width 1.8–2.3 mm ( $\bar{x} = 2.1$ ). (4) Head short (length/width ratio 0.87–0.92,  $\bar{x} = 0.90$ ). (5)

Gena slightly wider than eye, (6) rounded, not produced posteriorly. (10) Clypeal surface conspicuously depressed apicomedially. Labrum as in Figure 475; (24) distal process moderately well developed, pointed; (25) basal area depressed medially; (26) basal lateral depressions present, weakly developed. (30) Mandible extremely elongate, reaching midway between opposing clypeal angle and eye. (53) Clypeus obscurely granulate, shiny; (54) punctures distinct basally, becoming poorly defined and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: (75) Hairs on vertex, pronotum, mesoscutum, metanotum and scutellum white. Sternal vestiture as in Figure 483; (82) Hairs on sternum IV moderately elongate, suberect; (83) surface of sternum V with moderately short, suberect hairs, posterior edge with conspicuously elongate, rounded and well-separated hair lobes.

Terminalia: Sterna VII-VIII as in Figure 479; (85) median process of sternum VIII elongate. Genitalia as in Figures 480–482; (86) gonobase moderately elongate; (87) gonostylus elongate, slender; (89) retrorse membranous lobe moderately broad; (90) volsella with moderately produced lateral lobe.

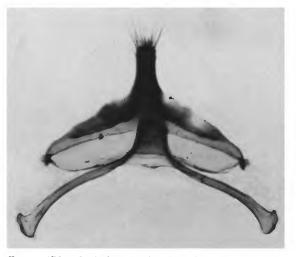

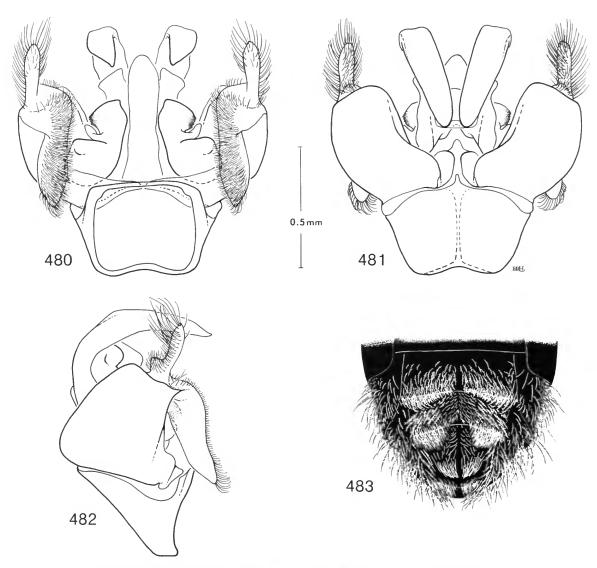

FIGURE 479.—Lasioglossum jubatum, male sterna VII-VIII.

FIGURES 480-483.—Lasioglossum jubatum, male: 480, genitalia, ventral view; 481, same, dorsal view; 482, same, lateral view; 483, sternal vestiture.

FLIGHT RECORDS.—Records for *L. jubatum* females range from March to October, with most records from June to August, with a peak in early July. Eleven of the 12 male records are from July through September; one male was taken on 16 February from the Mexican state of Morelos.

FLOWER RECORDS.—Females (17): Amaryllidaceae 71%; Compositae 24%. Total: 20 in 4

families, 6 genera as follows:

\*Agave 12(10)\$; Aplopappus 1\$; Baccharis 2\$, 16; Bidens 1\$; Buddleia 26; Quercus 1\$.

REMARKS.—The tentative sex association for L. jubatum is based primarily on the existence of two series of females and males taken from Chiapas and Chihuahua. Furthermore, the males (like

females), have short heads, conspicuous clypeal depressions, and complete to virtually complete pronotal lateral ridges. Unlike the females, the mesoscutal hairs of the males are white and concolorous with the pleural vestiture (female mesoscutal hairs are diagnostically orange to gold).

## 24. Lasioglossum katyae, new species

FIGURES 36, 395, 484

TYPE MATERIAL.—The female holotype is deposited in the Kansas University collection. It is in excellent condition and is labeled

COSTA RICA, Heredia Prov.[ince] 10 km. N. Heredia 25 July 1964 (Eickwort & Michener)/on Solanum tuberosum/ HOLOTYPE Lasioglossum katyae R.J. McGinley [red label].

Twelve female paratypes are also in the Cornell University Collection and one in the Oregon State Collection.

ETYMOLOGY.—This species is named after Kathleen P. Smith (Smithsonian Institution), who contributed to this study by photographing sterna VII-VIII of all *Lasioglossum* species and by translating Vachal (1904).

DISTRIBUTION (Figure 395).—Fourteen females of *L. katyae* are known to have been collected, 13 from Costa Rica and one from Guatemala.

DIAGNOSIS.—The large size (length 10.0–11.9,  $\tilde{x} = 10.5$ ), doubly-punctate mesoscutum with black mesoscutal hairs, and infuscated anterior edge of the forewing (as in Figure 235) will distinguish *L. katyae* from all other New World *Lasioglossum*. See *L. eickworti* diagnosis for further details.

DESCRIPTION.—FEMALE: (1) Length 10.0–11.9 mm ( $\bar{x} = 10.5$ , n = 12); (2) wing length 2.7–3.4 mm ( $\bar{x} = 3.0$ , n = 12); (3) abdominal width 2.6–3.0 mm ( $\bar{x} = 2.8$ , n = 12).

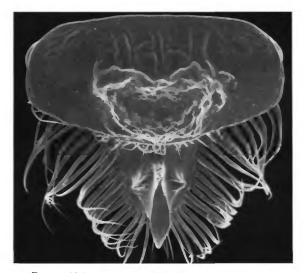

FIGURE 484.—Lasioglossum katyae, female labrum.

Structure: (4) Head moderately short (similar to Figure 396; length/width ratio 0.92-0.96,  $\bar{x} = 0.94$ , n = 12). (7) Supraclypeal area narrowly rounded dorsally along well-developed frontal carina, (8) area strongly protuberant. (9) Clypeus projecting approximately 0.88 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. (24) Labrum as in Figure 484; (27) distal keel broad in frontal view, lateral edges bowed; (28) distal lateral projections small but distinct, sharply triangular and projecting forward as in L. eickworti; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle very narrowly obtuse, sharply pointed; (33) pronotal lateral ridge incomplete, narrowly interrupted by oblique lateral sulcus; (34) upper portion of lateral ridge strongly carinate, lower portion rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.78 the length of scutellum and about 1.6 times the length of metanotum, (41) not depressed centrally, (42) posterior margin narrowly rounded; (43) propodeal triangle moderately well defined by low, median V-shaped elevation and carinate lateral rims, fading towards metanotum; (14) lateral carinae extending approximately two-thirds the length of posterior surface. (45) Tibial spur as in Figure 36.

(46) Lateral edge of metasomal tergum II broadly convex anteriorly, straight posteriorly.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming only slightly less dense near antennae. (51) Supraclypeal area obscurely granulate, shiny; (52) punctures separated by 1–2 times their width laterally, becoming sparsely punctate centrally. (53) Clypeus mostly polished, granulate along basal edge; (54) punctures obscure basally, separated by less than their width, very sparse apically, separated by 1–4 times their width. (56) Mesoscutum moderately shiny; (57) doubly-

punctate, smaller punctures separated by their width throughout, larger punctures separated by 3-4 times their width. (58) Scutellum nearly uniformly punctate, punctures fine, separated by 1-2 times their width. (63) Dorsal surface of propodeum strongly striate, striae not reaching posterior margin medially; (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures separated by less than their width but not quite contiguous.

Coloration: (71) Wing membrane pale yellowish brown, anterior one-quarter to one-third infuscated.

Vestiture: (74) Pubescence of head brown. (75) Pubsecence of thorax mostly dark brown, hairs white on pronotal lateral angle and pronotal lobe, pale yellowish brown on propodeum; (76) mesoscutal hairs moderately dense, conspicuously plumose. (77) Hind tibial hair color differentiated, ventral hairs golden, dorsal hairs dark brown. (78) Anterior hairs of metasomal tergum I pale yellowish brown, (79) basal hair bands of terga II-IV yellowish white. (80) Acarinarium absent, anterior surface of tergum I with short, adpressed hairs surrounded laterally by elongate hairs. (81) Unlike most species, hair band of tergum II very narrow, covering at most basal 0.25 of tergum, hair bands of terga II1-IV virtually absent, covering less than basal 0.25 of terga.

FLIGHT RECORDS.—One female was collected in late January, two in late June, and 11 in July.

FLOWER RECORDS.—Six females taken off Solanum tuberosum, 10 km north of Heredia, Costa Rica. Three of these females had nearly full pollen loads.

REMARKS.—L. katyae along with L. eickworti and L. sandrae probably comprise a natural taxon possibly deserving at least subgeneric status (see "Remarks" section for L. eickworti).

SPECIMENS EXAMINED.—149.

## 25. Lasioglossum lampronotum, new species

FIGURES 37, 485-490

TYPE MATERIAL.—The holotype female of Lasioglossum lampronotum is deposited in the Snow Museum, University of Kansas, Lawrence. The specimen is an excellent condition and is labeled.

21 mi. S.W. Prescott, [Yavapai County] Ariz.[ona] VII [July] -17-1950 C.D. Michener/Taken on Mentzelia pumila/HOL-OTYPE Lasioglossum lampronotum R.J. McGinley [red-label].

Sixty-three female paratypes and 10 male paratypes listed in the "Specimens Examined" section are designated.

ETYMOLOGY.—The specific epithet is derived from the Greek *lampros* (bright, brilliant) plus *notos* (back), a reference to the shiny mesoscutum characteristic of this species.

DISTRIBUTION (Figure 485).—Lasioglossum

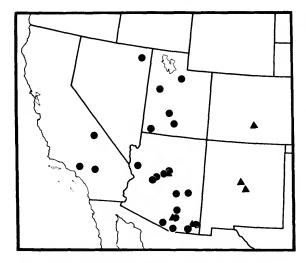

FIGURE 485.—Distribution of Lasinglossum lampronotum (circle) and L. rupticristum (triangle).

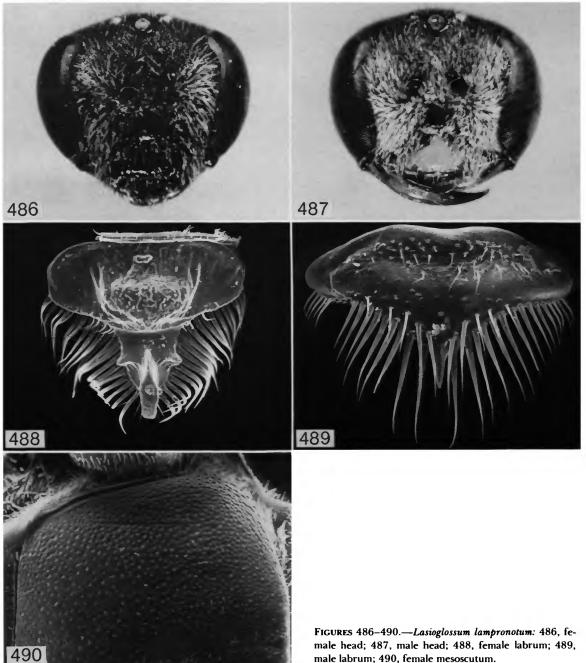

lampronotum is known from Arizona, southern California, Nevada, and Utah.

DIAGNOSIS.—Lasioglossum lampronotum can be recognized by the combination of its pale yellowish orange tarsi and hind tibiae, its short head (Figure 486), complete pronotal lateral carina, and shiny mesoscutum with dense but distinct punctures (Figure 490). It is most similar to L. heterorhinum but differs in having a polished clypeus (conspicuously granulate basally in L. heterorhinum), different mesoscutal punctation (L. heterorhinum mesoscutum dull, granuloso-punctate anteriorly, Figure 463) and pale leg color (legs entirely dark in L. heterorhinum). Lasioglossum rupticristum is also similar but differs in having an incomplete pronotal lateral carina as well as having entirely dark legs. See L. heterorhinum "Diagnosis" for further details.

DESCRIPTION.—FEMALE: (1) Length 7.8–9.6 mm ( $\bar{x} = 8.7$ , n = 15); (2) wing length 2.4–2.8 mm ( $\bar{x} = 2.6$ , n = 15); (3) abdominal width 2.4–2.8 ( $\bar{x} = 2.7$ , n = 15).

Structure: (4) Head short (Figure 486; length/width ratio 0.76–0.88, = 0.81, n = 15). (7) Supracylpeal area evenly rounded, (8) very weakly protuberant. (9) Clypeus projecting approximately 0.65 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. (24) Labrum as in Figure 488; (27) distal keel broad as seen in frontal view, slightly widest basally; (28) distal lateral projections well developed, triangular, and sharply pointed; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge complete (broad lateral sulcus reaching ridge but not distinctly interrupting it); (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.78 the length of scutellum and about 1.4 times the length of metanotum, (40) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident

medially as a low, inconspicuous, V-shaped elevation, lateral rims absent; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 37.

male labrum; 490, female mesoscutum.

(45) Lateral edge of metasomal tergum II weakly sinuate, nearly straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming only slightly less dense near antennae. (51) Supraclypeal area weakly granulate, (52) uniformly and densely punctate, punctures separated by their width. (53) Clypeus polished, obscurely granulate basally; (54) punctures separated by less than their width basally and medially to apex, sparsely punctate apicolaterally. (56) Mesoscutum very shiny; (57) punctation as in Figure 490, punctures very dense laterally, nearly contiguous, becoming granuloso-punctate along anterior edge, only slightly less dense centrally, punctures at most 2 times their width apart. (58) Scutellum nearly uniformly punctate, punctation similar to that of mesoscutum. (63) Dorsal surface of propodeum ruguloso-striolate laterally, becoming mostly rugulose medially (similar to that of L. heterorhinum, Figure 462); (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline. (72) Unlike most species, mid and hind tarsi, hind tibiae and distal quarter of mid tibiae usually pale yellowish orange (see "Remarks" section).

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white to yellowish white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hairs concolorous, yellowish white. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 7.0–7.8 mm ( $\bar{x}=7.4$ , n=2); (2) wing length 2.0–2.1 mm ( $\bar{x}=2.1$ , n=2); (3) abdominal width 1.8–1.9 mm ( $\bar{x}=1.9$ , n=2). (4) Head as in Figure 487 (length/width ratio 0.82,  $\bar{x}=0.82$ , n=2). (5) Gena narrower than eye, (6) strongly produced posteriorly, angulate. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 489; (24) distal process developed as an elongate, acute projection: (25) basal area only moderately depressed medially; (26) basal lateral depressions moderately developed. (30) Mandible moderately elongate, reach-

ing just beyond opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed and dense basally, apical two-thirds sparsely punctate with mixture of very fine and larger, poorly defined punctures. (69) Flagellum paler on venter than on dorsal surface. (72) Tarsi yellowish white. Vestiture and terminalia as described for *L. heterorhinum*.

FLIGHT RECORDS.—Lasing lossum lampronotum females have been collected from March through August. The one female taken in March was from Cochise County, Arizona; the one April record was from Mohave County, Arizona. The three known males were taken in July, August, and September.

FLOWER RECORDS.—Females (26): Solanaceae 38%; Loasaceae 31% Rosaceae 12%. Male (1): Compositae 100%. Total: 27 in 8 families, 10 genera as follows:

Agave 19; Astragalus 19; Baccharis 19; Cowania 39; \*Mentzelia 8(8)9; Nicotiana 19; Phacelia 19; Salvia 19; Senecio 18; Solanum 99.

REMARKS.—The tarsi and hind tibiae of most Lasioglossum lampronotum specimens are conspicuously pale yellowish orange but there is some variability in this feature. Five of the 60 females examined had at least partially darkened hind legs: three females from Wild Rose Canyon, Inyo County, California, had the tarsi and tibiae of all legs darkly pigmented; one female from Box Canyon and another from the Santa Catalina Mountains, Pima County, Arizona, had just the hind tibiae darkly pigmented.

Halictus leucozonius. — Dalla Torre, 1896:66 [World catalog; covers older literature]. — Atwood, 1933:449 [biology]. — Sandhouse, 1933:78 [taxonomic notes].

Lasinglossum leucozonium.—Michener, 1951:1106 [Nearctic catalog].—Evans and Lin, 1959:127, 130 [predators, Phi-

lanthus bilunatus Cresson, P. solivagus Say].—Mitchell, 1960:338, 344 [key, redescription].—Knerer and Atwood, 1962:163 [locality and flower records].—Knerer, 1968:83; 1969:141-144 [biology notes].—Knerer and MacKay, 1969:290-293.—Evans, 1975:891 [predator, Philanthus albopilosus Cresson].—Hurd, 1979:1957 [Nearctic catalog].—Duffield et al., 1981:323 [Dufour's gland chemistry].

Type Material.—The type of Apis leucozonia was not examined. The female holotype of Halictus similis, in the British Museum (Natural History), is labeled

Type H.T. [on circular label with orange-red border]/B.M. TYPE HYM. 17a.995/B.M. TYPE HYM. Halictus similis Smith 1853/similis Sm[ith] Type [handwritten].

The specimen is in fair condition, missing both antennae, the left front leg, the distal tarsomere of the left hind leg, and the tarsus of the right hind leg.

DISTRIBUTION (Figure 491).—Lasioglossum leucozonium is a holarctic species, widespread in Europe. In the New World, L. leucozonium occurs from Cape Breton Island south to New Jersey and west to Wisconsin. An isolated record is one female collected in 1974 from Blount Co., Tennessee (University of Kansas Collection). Future collecting in the Appalachians may produce more

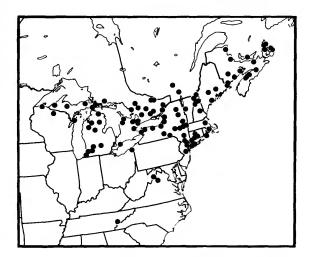

FIGURE 491.—New World distribution of Lasinglossum leucozonium.

southern records for this species.

DIAGNOSIS.—In the eastern United States, Lasioglossum leucozonium and L. zonulum are the only female Lasioglossum that have a strongly striate to reticulate dorsal propodeal surface (Figures 496, 738; in other species the surface is smooth posteriorly, Figure 358, to completely ruguloso-striolate, Figure 438). The dorsal propodeal surface of both species is nearly unique in being conspicuously short, only slightly longer than the metanotum (L. titusi, a western species, has a similarly short propodeal surface, Figure 636). The first metasomal tergum of L. leucozonium is dull with well-developed punctures separated by 1-1.5 times their width (Figure 139; tergum shiny, punctures very fine and sparse in L. zonulum, Figure 138). The pronotal lateral angle of L. zonulum is more strongly projecting than that of L. leucozonium (Figures 497, 739), and the latter species can be further differentiated from L. zonulum and other Lasioglossum in having conspicuous transverse striations on the vertex behind the ocelli (Figure 140; striations absent or weakly developed in other species).

Males of Lasioglossum leucozonium have a dense patch of hairs on the posterior edge of sternum V and a unique inverted V-shaped hair patch on sternum VI (Figure 204). Other characters helpful in recognizing L. leucozonium males are the rounded clypeus and ventrally narrowed head (Figure 493), the coarsely rugose dorsal propodeal surface, and the yellow basitarsi of the middle and hind legs.

DESCRIPTION.—FEMALE: (1) Length 8.2–10.0 mm ( $\bar{x} = 9.0$ , n = 15); (2) wing length 2.2–2.5 mm ( $\bar{x} = 2.4$ , n = 15); (3) abdominal width 2.8–33. ( $\bar{x} = 3.1$ , n = 15).

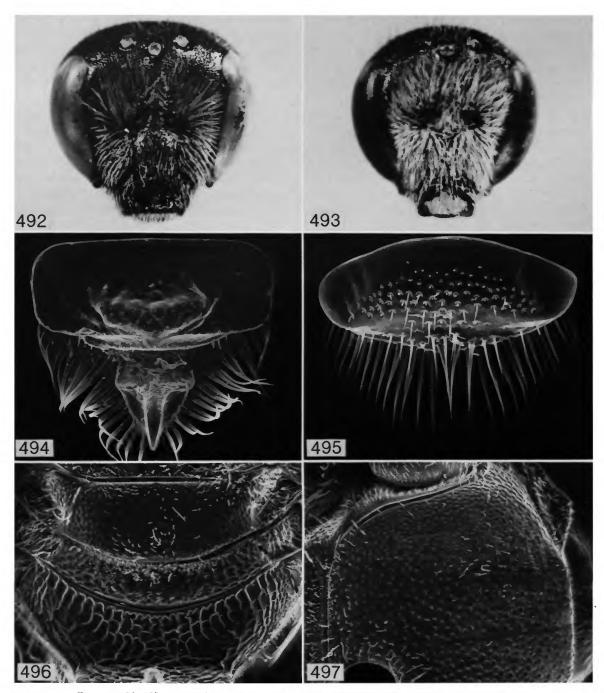

Structure: (4) Head elongate (Figure 492; length/width ratio 0.88-0.96,  $\bar{x}=0.92$ , n=15). (7) Supraclypeal area evenly rounded, (8) very weakly protuberant. (9) Clypeus projecting approximately 0.86 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli exceeding distance between lateral ocellus and eye. (23) Flagellomere 1 longer than 2 along

dorsal surface. Labrum as in Figure 494; (27) distal keel moderately broad in frontal view, gradually narrowing towards apex (similar to *L. zonulum*); (28) distal lateral projections moderately well developed, weakly projecting; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle moderately obtuse (dorsal edge of pronotum well developed); (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip rounded, not bilobed, (36) strongly elevated from pronotum. (40) Dorsal surface of propodeum about 0.61 the length of scutellum and subequal in length to metanotum, (41) not depressed centrally, (42) posterior margin indistinctly truncated (lateral angles of dorsal surface gradually sloping from propodeal triangle); (43) propodeal triangle well defined by carinate rim; (44) lateral carinae extending to dorsal surface, becoming indistinct medially. (45) Tibial spur as in Figure 38.

(46) Lateral edge of metasomal tergum II only faintly sinuate, virtually straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area extremely granulate; (52) uniformly and densely punctate, punctures separated by their width or less. (53) Clypeus shiny but obscurely granulate; (54) punctures dense, nearly contiguous basally and medially to apex, slightly less dense apicolaterally. (56) Mesoscutum moderately shiny, surface microscopically patterned; (57) punctation as in Figure 497, punctures coarse, separated by their width or less laterally, obscurely formed anteriorly, separated by 2-3 times their width centrally. (58) Scutellum nearly uniformly punctate, punctation similar to that of mesoscutum. (63) Dorsal surface of propodeum (Figure 496) strongly striate laterally, becoming reticulate medially, striae and rugae reaching posterior margin; (64) surface smooth, not alveolated. (65) Metasomal tergum I moderately shiny, granulate; (66) punctation well defined, punctures deep, separated by 1-1.5 times NUMBER 429

FIGURES 492-497.—Lasioglossum leucozonium: 492, female head; 493, male head; 494, female labrum; 495, male labrum; 496, female propodeum; 497, female mesoscutum.

their width posteriorly, less dense anteriorly, separated by 1-2 times their width.

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white to yellowish white. (75) Pubescence of thorax white to yellowish white with some brown hairs on scutellum; (76) mesoscutal hairs moderately dense, conspicuously plumose. (77) Hind tibial hair color weakly differentiated, most hairs pale yellowish brown, dorsal hairs light brown. (78) Anterior hairs of metasomal tergum 1 and (78) basal hair bands of terga I1–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 7.2–8.8 mm ( $\bar{x} = 7.4$ , n = 15); (2) wing length 1.6–2.1 mm ( $\bar{x} = 1.8$ , n = 15); (3) abdominal width 1.8-2.3 ( $\bar{x} = 2.0$ , n = 15). (4) Head as in Figure 493 (length/width ratio 0.95-1.04,  $\bar{x}$ = 0.98, n = 15). (5) Gena wider than eye, (6) rounded, not produced posteriorly. (10) Clypeal surface broadly rounded, not flattened or depressed. Labrum as in Figure 495; (24) distal process weakly developed, rounded; (25) basal area with small circular median depression, mostly evenly rounded; (26) basal lateral depressions weakly developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus weakly granulate, shiny; (54) uniformly punctate throughout, punctures separated by less than their width. (68) Clypeal maculation present (Figure 493). (69) Flagellum entirely dark or with ventral surface slightly paler than dorsum. (72) Foretarsi entirely dark; middle and hind basitarsi yellowish white except for dark distal edges, contrasting with tibiae and other tarsal segments; bases of middle, hind, and usually foretibiae with pale basal maculation.

Vestiture: Sternal vestiture as in Figure 204; (82) hairs on sternum IV erect, elongate without noticeable pattern; (83) posterior half of sternum V with dense patch of conspicuous, adpressed hairs; (84) unlike other New World Lasioglossum species except L. zonulum, sternum VI with a highly characteristic hair pattern consisting of a unique, inverted V-shaped hair patch.

Terminalia: Sterna VII-VIII as in Figure

502; (85) sternum VII somewhat reduced, slender, similar to that of *L. zonulum*; sternum VIII without median process; like *L. zonulum*, sternal disc reduced, narrow. Genitalia as in Figures 498–501; (86) gonobase moderately short; (87) gonostylus large, flat, rounded apically (unlike most species except *L. zonulum*, gonostylus with only short, inconspicuous setae); (88) retrorse membranous lobe absent; (90) volsella with prominent lateral flange.

FLIGHT RECORDS (Figure 503).—In the New World, Lasioglossum leucozonium females have been collected from late May through October, with most records from early June. Most male records are from late July and August but range from June through October.

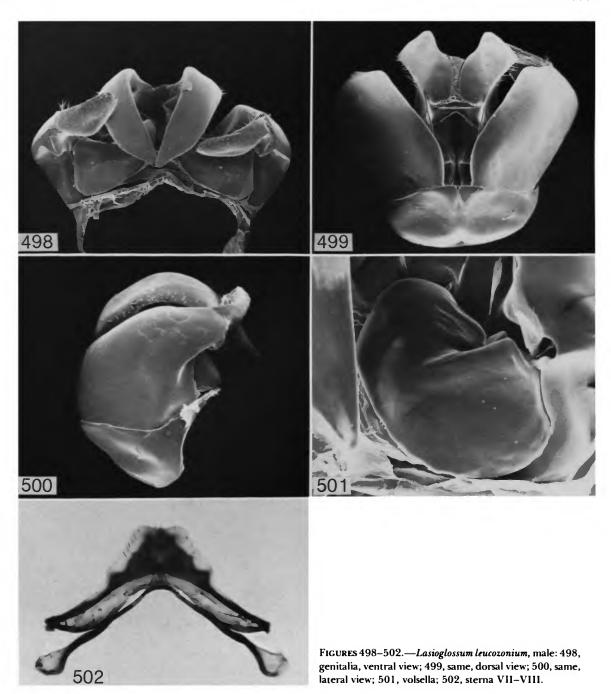

FLOWER RECORDS.—Floral label data suggests that L. leucozonium shows a preference for flowers of the Compositae; 89% of the female records and 64% of the male records were from composite genera. Of the 78 females noted to have scopal pollen loads, 74 (95%) were taken from members of this family (the exceptions were one female from Campanula and 3 females from Rosa). Males, unlike females, were also commonly found on Melilotus (80 records).

Summary: Females (212): Compositae 89%; Rosaceae 5%. Males (573): Compositae 64%; Leguminosae 16.4%; Polygonaceae 7%. Total: 785 in 13 familes, 34 genera as follows:

\*Achillea 2(2)\$\(\frac{2}{2}\); Anaphalis 12\(\delta\); Arctium 7\(\delta\); Aster 1\(\text{9}\), 8\(\delta\);
Barbarea 1\(\text{9}\); \*Campanula 3(1)\$\(\text{9}\); 2\(\delta\); \*Centaurea 7(2)\$\(\text{9}\), 8\(\delta\);

### 27. Lasioglossum manitouellum (Cockerell)

FIGURES 39, 504-518

Halictus manitouellus Cockerell, 1908:119 [female].
Halictus manitonellus.—Cockerell, 1910a:260 [lapsus calami].

Lasioglossum manitouellum.—Michener, 1951:1106 [Nearctic catalog].—Hurd, 1979:1957 [Nearctic catalog].—Evans, 1982:573 [predator, Philanthus barbatus Smith].

TYPE MATERIAL.—Cockerell described Lasioglossum manitouellum from a syntype series of four females. Only two of these specimens could be located, and the one labeled "TYPE" by Cockerell is herein designated the lectotype. This specimen, in the University of Colorado Collection at Boulder, is labeled

T.D.A. & W.P. Cockerell./Manitou ([El Paso County], Col.[orado], Apr. 29 [19]04 [handwritten] TYPE [handwritten by Cockerell with red ink lines bordering lateral edges of label]/LECTOTYPE Halictus manitouellus Cockerell des.[ignated by] McGinley [handwritten on red label].

The lectotype is missing the last two tarsomeres of the middle left leg but otherwise is in excellent condition. The one known paralectotype is in the National Museum of Natural History, Smithsonian Institution.

DISTRIBUTION (Figure 504).—The latest Nearctic Hymenoptera catalog (Hurd, 1979) reports Lasioglossum manitouellum only from Colorado. This species is now known to occur in Arizona, Colorado, Kansas, New Mexico, Texas, and south into Chihuahua, Mexico. Two anomalous females from Hidalgo and Chiapas, Mexico, are herein only tentatively associated with L. manitouellum.

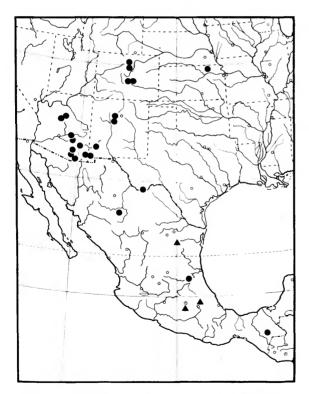

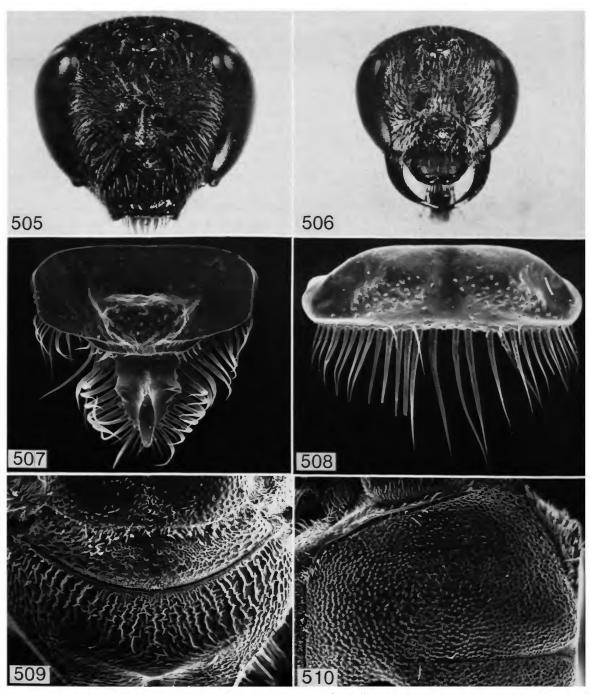

FIGURE 504.—Distribution of Lasioglossum manitouellum (circle) and L. xyriotropis (triangle).

DIAGNOSIS.—Females of Lasioglossum manitouellum can be recognized by the combination of their entirely granuloso-punctate mesoscuta (Figure 510), moderately short heads (Figure 505), lack of acarinaria, and hyaline forewings with infuscated apices (Figure 229). The entirely granuloso-punctate mesoscutum is characteristic of many Mexican Lasioglossum species but is found in only three species occurring in the United States: L. manitouellum, L. acarophilum, and L. jubatum. The latter two species differ from L. manitouellum in having large acarinaria on the anterior surface of tergum I (Figures 247, 478). Lasioglossum heterorhinum, L. lampronotum, and L. desertum have the anterior mesoscutal surface granuloso-punctate but the punctures are distinctly separated posteriorly. Among Mexican species, L. xyriotropis is most similar to L. manitouellum but differs by having a complete pronotal lateral carina (Figure 732; narrowly but distinctly interrupted in L. manitouellum). Lasioglossum transvorsum and L. asaphes are superficially similar to L. manitouellum but have longer heads (Figures 275, 646) and differ in other details listed in the diagnosis for both species.

Lasioglossum manitouellum males are best diagnosed by the combination of their short heads (Figure 506), hyaline forewings with infuscated apices, and the elongate, lateral hair fringes on the posterior edge of sternum V (Figure 511). The vestiture of sternum V is very similar to that of Lasioglossum heterorhinum and L. lampronotum males (Figure 464). However, the latter species do not have infuscated forewing apices and have conspicuously complete pronotal lateral carinae (distinctly interrupted in L. manitouellum males).

DESCRIPTION.—FEMALE: (1) Length 8.3-10.6 mm ( $\bar{x} = 9.5$ , n = 15); (2) wing length 2.7-3.1 mm ( $\bar{x} = 2.9$ , n = 15); (3) abdominal width 2.5-3.1 mm ( $\bar{x} = 2.9$ , n = 15).

Structure: (4) Head moderately short (Figure 505; length/width ratio 0.85–0.96,  $\bar{x} = 0.91$ , n = 15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.69 of its length below lower margin of eyes; (11) surface with narrow median

FIGURES 505-510.—Lasioglossum manitouellum: 505, female head; 506, male head; 507, female labrum; 508, male labrum; 509, female propodeum; 510, female mesoscutum.

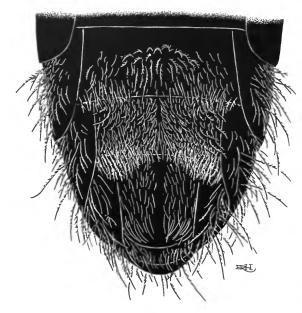

FIGURE 511.—Lasioglossum manitouellum, male sternal ves-

longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 shorter than 2 along dorsal surface. Labrum as in Figure 507; (27) distal keel moderately broad in frontal view, lateral edges bowed; (28) distal lateral projections moderately well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.74 the length of scutellum and about 1.2 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident medially as an inconspicious V-shaped elevation, lateral rims absent; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 39.

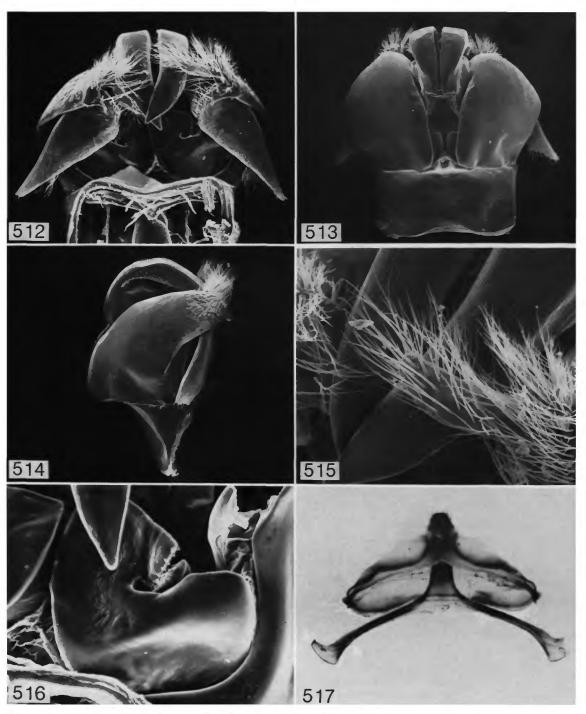

(46) Lateral edge of metasomal tergum II weakly sinuate, nearly straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, only slightly less dense near antennae. (51) Supraclypeal area extremely granulate; (52) punctures separated by their width laterally, becoming less dense centrally. (53) Clypeus granulate basally, apical two-thirds polished; (54) punctation sparse, punctures separated by their width basally, becoming obscure apically, apicolateral areas impunctate. (56) Mesoscutum mostly moderately shiny, dull on median anterior portion; (57) punctation as in Figure 510, granulosopunctate, less dense posteriorly. (58) Scutellum nearly uniformly punctate, punctures less dense than those of mesoscutum, punctures separated by their width or slightly less. (63) Dorsal surface of propodeum (Figure 509) irregularly striate laterally, becoming ruguloso-striolate medially, striae and rugulae reaching posterior margin or nearly so; (64) surface shiny, mostly smooth, alveolate only along extreme basal edge. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration: (71) Wing membrane mostly hyaline with conspicuous infuscated apex beyond marginal cell.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax mostly white, pale yellowish brown on scutellum; (76) mesoscutal hairs sparse, inconspicuous, obscurely plumose. (77) Hind tibial hair color differentiated, most hairs white, dorsal hairs dark brown basally, becoming white at tibial midpoint. (78) Anterior hairs of metasomal tergum I white; (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 6.9–8.2 mm ( $\bar{x}=7.5$ , n=10); (2) wing length 2.3–2.7 mm ( $\bar{x}=2.5$ , n=10); (3) abdominal width 1.9–2.1 mm ( $\bar{x}=2.0$ , n=10). (4) Head as in Figure 506 (length/width ratio 0.87–0.96,  $\bar{x}=0.91$ , n=10). (5) Gena slightly wider than eye, (6) strongly produced posteriorly. (10) Clypeal surface flat. Labrum as in Figure 508;

FIGURES 512-517.—Lasioglossum manitouellum, male; 512, genitalia, ventral view; 513, same, dorsal view; 514, same, lateral view; 515, gonostylus; 516, volsella; 517, sterna VII-VIII.

(24) distal process absent; (25) basal area depressed medially; (26) basal lateral depressions conspiciously developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate along basal edge, apical two-thirds polished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 511; (82) hairs on sternum IV erect, moderately elongate, without noticeable pattern; (83) sternum V with median rosette of short erect hairs, posterior sternal edge with moderately elongate, widely separated lateral hair lobes.

Terminalia: Sterna VII-VIII as in Figure 517; (85) sternum VIII with short, narrowly rounded median process. Genitalia as in Figures 512-516; (86) gonobase moderately elongate; (87) gonostylus slender, moderately elongate, apex narrowly rounded; (89) retrorse membranous lobe broad; (90) volsella with broadly rounded lateral lobe.

FLIGHT RECORDS (Figure 518).—Lasioglossum manitouellum females have been collected in every month from February to December, with peaks in later March and again in early October. The early records are two females, Cochise Co., Arizona, 19 Feb 1963; one female, Pima Co., Arizona, 22 Feb 1956. The late records are two females, 1–10 Nov 1965, Cochise Co.; one female, 11 Nov 1953, Pima Co.; one female, 11 Nov 1953, Pima Co.; one female, 10 Dec 1967, Cochise Co. Males have been collected in May, July through October, and in December. The one May record was from Nuevo Leon (near Monterrey), Mexico. The two December records were from Cochise Co., Arizona.

FLOWER RECORDS.—Females (71): Compositae 31%; Rosaceae 22%; Ericaceae 18%; Anacardiaceae 13%. Total: 71 in 12 families, 13 genera as follows:

Arctostaphylos 129; Ceanothus 39; Cimicifuga \*1(1)9 (collecting pollen, 0. Pellmyr, pers. comm.); Geranium 19; Melilotus 19; Nolina 19; \*Penstemon 1(1)9 (tentatively associated female from Hidalgo); Prunus 159; Rhus 99; Salix 39; Solanum 39; Solidago 39; Viguiera 189.

## 28. Lasioglossum morrilli (Cockerell)

FIGURES 41, 519-530

Halictus morrilli Cockerell, 1918a:178 [female].
Lasioglossum morrilli.—Michener, 1954:40 [taxonomic notes; Lasioglossum morrilli was not recorded in the 1951 and 1979 Nearctic catalogs].

TYPE MATERIAL.—The female holotype, in the National Museum of Natural History, Smithsonian Institution, is in good condition but is glued by its venter on top of a paper point. Darkened glue (shellac?) obscures much of the venter and right hind leg and also adheres to portions of both pairs of wings. The last two tarsomeres of the left hind leg are missing. The holotype is labeled

Tlahualico Durango Mex.[ico] 3 [Mar] 9 [19]'04/at peach blossums/A W Morrill Collector/Type No. 23214 U.S.N.M. [red label]/Halictus morrilli Ckll. [Cockerell] TYPE [handwritten by Cockerell].

There are no paratypes, because Cockerell described this species from the unique female known to him.

DISTRIBUTION (Figure 519).—Lasioglossum morrilli is presently known from only 71 specimens (619, 108) that have been collected in southern Arizona, New Mexico, Texas, and northern Mexico (Chihuahua, Durango, Nuevo Leon). Most specimens are from Texas.

DIAGNOSIS.—Lasioglossum morrilli has the fol-

lowing unique character combination: acarinarium present on anterior surface of metasomal tergum I (Figure 525) with dorsal acarinarial opening narrower than width of lateral hair fringe as seen in dorsal view; head elongate (Figure 520, length/width ratio 0.86-0.96,  $\bar{x}=0.90$ ); wing membrane hyaline; clypeus and supraclypeal area conspicuously polished, not at all granulate.

Lasioglossum bardum, L. desertum, and L. jubatum are superficially similar to and are sympatric or nearly sympatric with L. morrilli but differ in having short heads (Figures 303, 381, 473) and granulate clypeal and supraclypeal surfaces. Furthermore, L. desertum and L. jubatum have very wide dorsal acarinarial openings (Figures 393, 478).

Among species having acarinaria and elongate heads, L. paraforbesii occurs south only to Colorado and Kansas but is also easily distinguished by its pale yellowish brown wing membranes. Lasioglossum acarophilum has a distinctive granuloso-punctate mesoscutum (Figure 251; compare with Figure 524) and a wide dorsal acari-

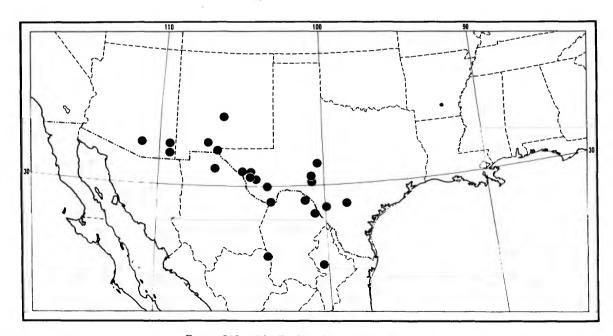

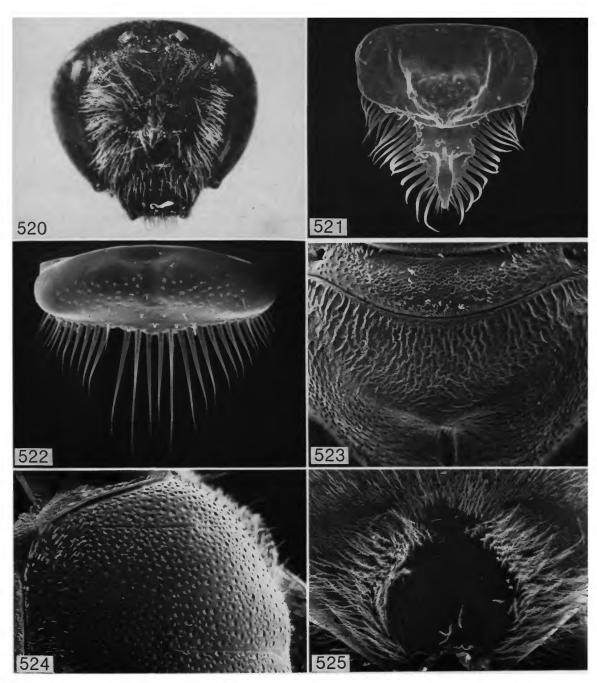

FIGURE 519.—Distribution of Lasioglossum morrilli.

FIGURES 520-525.—Lasioglossum morrilli: 520, female head; 521, female labrum; 522, male labrum; 523, female propodeum; 524, female mesoscutum; 525, female acarinarium at base of tergum I.

narial opening (Figure 247). Lasioglossum egregium and L. trizonatum are very similar to L. morrilli but can be differentiated by the shape of the lateral edge of metasomal tergum II: virtually straight in L. egregium (Figure 63), sinuate in L. morilli (similar to Figure 61), conspicuously sinuate in L. trizonatum (as in Figure 64). The acarinaria of L. egregium and L. trizonatum are less sharply delimited than that of L. morrilli and have wider dorsal acarinarial openings (Figures 693, 711). The former two species also usually have lightly pigmented wing membranes (always hyaline in L. morrilli) and granulate clypeal and supraclypeal surfaces.

The elongate head, rounded and virtually impunctate clypeus, and lack of elongate hairs on sternum V will distinguish the male of L. morrilli from those of other New World Lasioglossum. In its range, the male of L. morrilli is most similar to that of L. manitouellum; however, the males of the latter species have a flat clypeus, infuscated forewing tips (hyaline in L. morrilli) and elongate lateral hair fringes on sternum V.

DESCRIPTION.—FEMALE: (1) Length 8.3-9.7 mm ( $\bar{x} = 9.2$ , n = 15); (2) wing length 2.5-2.8 mm ( $\bar{x} = 2.7$ , n = 15); (3) abdominal width 2.6-3.0 mm ( $\bar{x} = 2.8$ , n = 15).

Structure: (4) Head elongate (Figure 520; length/width ratio 0.86-0.96,  $\bar{x}=0.90$ , n=15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.91 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli exceeding distance between lateral ocelli exceeding distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 521; (27) distal keel moderately broad in frontal view, lateral edges bowed, with conspicuous basal median groove; (28) distal lateral projections moderately well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower por-

tion of lateral ridge broadly rounded. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.75 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident medially as a low V-shaped elevation, lateral rims inconspicuous; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 41.

(46) Lateral edge of metasomal tergum II moderately sinuate.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area highly polished; (52) punctures separated by their width laterally, impunctate centrally. (53) Clypeus highly polished; (54) punctures separated by less than width basally, apical edge and apicolateral areas impunctate or nearly so. (56) Mesoscutum shiny; (57) punctation as in Figure 524, punctures separated by 1.5 times their width or less laterally, becoming very sparse centrally, punctures 2-5 times their width apart. (58) Scutellum sparsely and finely punctate adjacent to median line, punctures separated by 1-3 times their width. (63) Dorsal surface of propodeum (Figure 523) ruguloso-striolate, often becoming rugulose medially, striae and rugulae reaching posterior margin; (64) surface alveolated. (65) Metasomal tergum 1 moderately shiny; (66) punctation fine, dense punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hairs concolorous, all white, or with light brown dorsal hairs at base. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga I1–IV white. (80) Acarinarium present (Figure 525), a moderately large, circular, glabrous area surrounded laterally and dorsally by

dense fringe of elongate hairs, dorsal opening of acarinarium narrow, width of opening approximately one-half the width of lateral hair fringe as seen in dorsal view; each side of tergum I with small bald spot posteriad of lateral acarinarial hair fringe.

MALE: Similar to female except as follows: (1) length 7.6-9.0 mm ( $\bar{x} = 8.2$ , n = 6); (2) wing length 2.0-2.4 mm ( $\bar{x} = 2.2$ , n = 6); (3) abdominal width 2.1-2.6 mm ( $\bar{x} = 2.2$ , n = 6). (4) Head elongate (length/width ratio 0.91-1.0,  $\bar{x} = 0.95$ , n = 6). (5) Gena slightly wider than eye, (6) moderately produced posteriorly. (10) Clypeal surface noticeably rounded dorsally, contrasting with shallowly depressed ventral area. Labrum as in Figure 522; (24) distal process very weakly developed, rounded; (25) basal area depressed medially; (26) basal lateral depressions absent. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed and dense basally, apical twothirds virtually impunctate, punctures very fine and scattered. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: (82) Hairs on sternum IV elongate, erect, without noticeable pattern; (83) sternum V with inconspicuous median rosette of short hairs but otherwise without noticeable hair patterns.

Terminalia: Sterna VII-VIII as in Figure 530; (85) sternum VIII with moderately elongate, parallel-sided median process, rounded apically. Genitalia as in Figures 526–529; (86) gonobase moderately elongate; (87) gonostylus moderately robust, truncated apically; (89) retrorse membranous lobe very slender; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS.—Lasioglossum morrilli females have been collected from late February through November, with most records from May. Five of the known males were collected in early August, one in early September (one with no data).

FLOWER RECORDS.—Females (8): Compositae

25%. Males (3): Compositae 100%. Total: 11 in 7 families, 9 genera as follows:

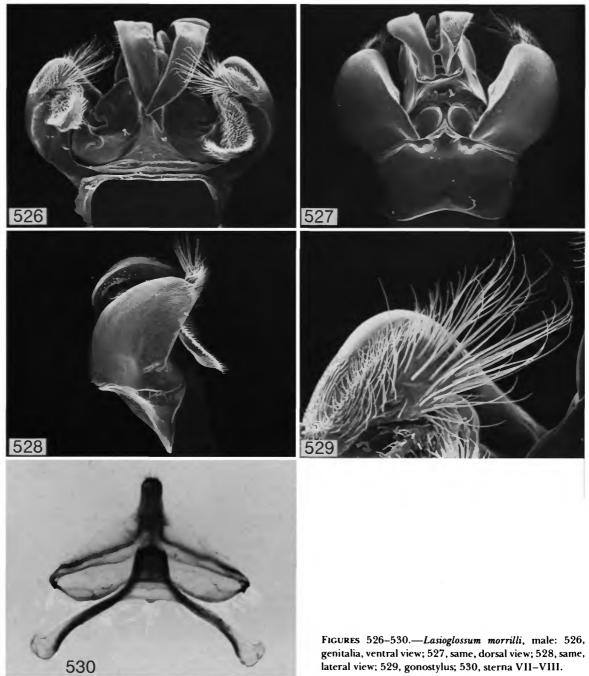

Arctostaphylos 19; Cirsium 19; Citris 19; Coreopsis 19; Dasylirion 19; Helenium 38; Lippia 19; Prunus 19; Solanum 19.

## 29. Lasioglossum olympiae (Cockerell)

FIGURES 42, 203, 531-544

Halictus olympiae Cockerell, 1898b:51 [female].—Vachal, 1904:476 [male].

Lasioglossum olympiae.—Michener, 1951:1107 [Nearctic catalog].—Moldenke and Neff, 1974:53 [locality and flower records, sex ratio].—Hurd, 1979:1957 [Nearctic catalog].

TYPE MATERIAL.—The female holotype, in the National Museum of Natural History, Smithsonian Institution, is in good condition. It is labeled

Olympia, [Thurston County], Wash.[ington]/6[June] 26 [18] 96/Type No. 29420 U.S.N.M. [red label]/H.[alictus] olympiae n. sp. [handwritten by Cockerell].

There were no paratypes designated.

Halictus olympiae var. subangustus, long thought to be a junior synonym of Lasioglossum olympiae, is herein reported to be a junior synonym of L. sisymbrii.

DISTRIBUTION (Figure 531).—Lasioglossum olympiae is presently known from north and central California, Idaho, Oregon, Washington, and Vancouver Island. It does not occur in Colorado as was tentatively reported in both nearctic catalogs.

DIAGNOSIS.—The strong, regular striations of the propodeal dorsal surface (Figure 536) will distinguish Lasioglossum olympiae from all other New World Lasioglossum except L. leucozonium, L. zonulum, L. pacificum, L. timberlakei, and L. sisymbrii. Lasioglossum leucozonium and L. zonulum have relatively longer heads than that of L. olympiae (Figures 492, 532, 734), coarser mesoscutal punctation (Figures 497, 537, 739), and a conspicuously short propodeal dorsal surface

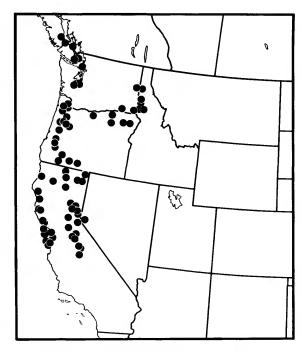

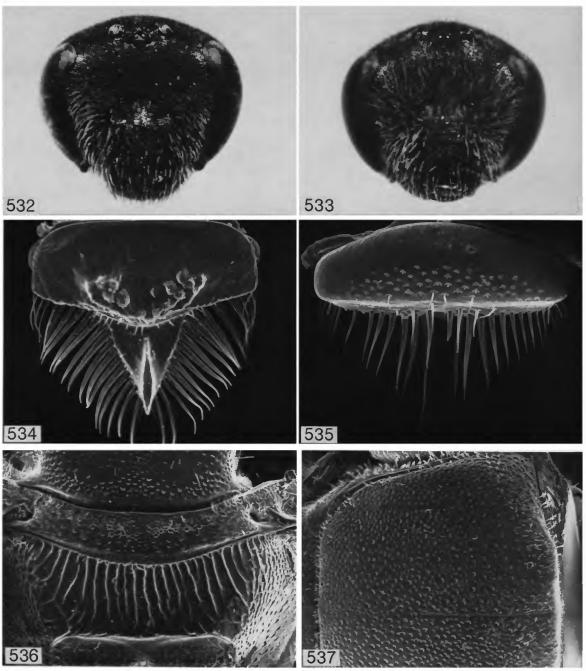

FIGURE 531. -- Distribution of Lasinglossum olympiae.

that is only slightly longer than the metanotum (Figures 496, 738; noticeably longer than metanotum in L. olympiae as in most other species). Lasioglossum sisymbrii is easily differentiated from L. olympiae by the former species' basal hair band on tergum I (Figure 132) and its pale, translucent tegulae. The most similar species to L. olympiae are L. pacificum and L. timberlakei (especially the dark form). They differ from L. olympiae in having the posterior edge of the propodeal dorsal surface slightly bowed posteriad as seen in dorsal view (Figure 559; sharply truncated in L. olympiae, Figure 536). Furthermore, L. pacificum and L. timberlakei (dark form) have the dorsal propodeal striations more widely spaced than those of L. olympiae (Figures 536, 559, 623), the area immediately dorsoanteriad of the middle coxa striolated and dull (Figure 147; relatively smooth and polished in L. olympiae, Figure 146), and the head and body pubescence generally pale yellowish brown to golden (white in L. olympiae).

Males of L. olympiae can be recognized by the unique vestiture of sternum V, characterized by

FIGURES 532-537.—Lasioglossum olympiae: 532, female head; 533, male head; 534, female labrum; 535, male labrum; 536, female propodeum; 537, female mesoscutum.

a median, longitudinal patch of short, dense hairs (Figure 203). Also helpful in identifying these males (but not unique) is the strongly striate dorsal propodeal surface and the lack of a clypeal maculation.

DESCRIPTION.—FEMALE: (1) Length 7.6–9.6 mm ( $\bar{x} = 8.9$ , n = 15); (2) wing length 2.3–2.8 mm ( $\bar{x} = 2.6$ , n = 15); (3) abdominal width 2.7–3.1 mm ( $\bar{x} = 3.0$ , n = 15).

Structure: (4) Head short (Figure 532; length/width ratio 0.77-0.88,  $\bar{x} = 0.83$ , n = 15). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.78 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 534; (27) distal keel narrow in frontal view, lateral edges slightly bowed; (28) distal lateral projections virtually absent, evident as obscure swellings; (29) fimbrial setae acutely pointed (unlike other species, sensillae on basal elevation on conspicuous, wart-like swellings).

(32) Pronotal lateral angle moderately obtuse; (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip rounded, not bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.69 the length of scutellum and about 1.2 times the length of metanotum, (41) not depressed centrally, (42) posterior margin sharply truncated; (43) propodeal triangle weakly defined laterally; (44) lateral carinae completely encircling posterior surface. (45) Tibial spur as in Figure 42.

(46) Lateral edge of metasomal tergum 11 weakly sinuate, nearly straight.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) uniformly and densely punctate, punctures separated by their width or less. (53) Clypeus granulate basally and medially

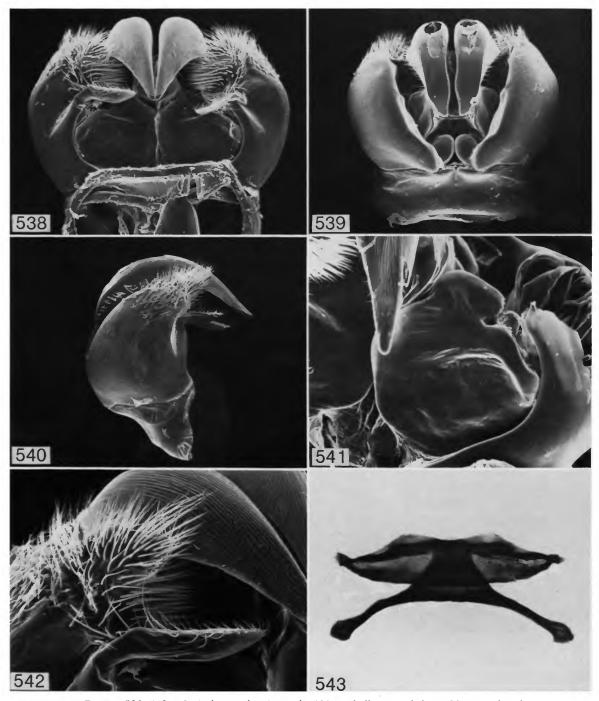

to apex, apicolateral areas polished; (54) punctures separated by less than their width basally, becoming less dense apically. (56) Mesoscutum shiny; (57) punctation as in Figure 537, nearly uniform, punctures 1–2 times their width apart, granuloso-punctate along anterior edge. (58) Scutellum sparsely punctate adjacent to midline, punctures 2–3 times their width apart. (63) Dorsal surface of propodeum (Figure 536) strongly and completely striated, striae closer together medially than laterally, usually with obscure regulae in median sulcations; (64) surface smooth, not alveolated. (65) Metasomal tergum I shiny; (66) punctation fine, moderately sparse, punctures about 2 times their width apart.

Coloration: (71) Wing membrane nearly hyaline, very lightly pigmented.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white to yellowish white; (76) mesoscutal hairs moderately dense, conspicuously plumose. (77) Hind tibial hair color differentiated, mostly white to pale yellowish brown, dorsal hairs dark brown to brown. (78) Anterior hairs of metasomal tergum 1 and (79) basal hair bands of terga 11–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 6.2-7.8 mm ( $\bar{x} = 7.0$ , n = 15); (2) wing length 1.8-2.3 mm ( $\bar{x} = 2.0$ , n = 15); (3) abdominal width 2.0-2.5 mm ( $\bar{x} = 2.3, n = 15$ ). (4) Head as in Figure 533 (length/width ratio 0.76-0.95,  $\bar{x} = 0.86$ , n = 15). (5) Gena subequal to eye in width, (6) rounded, not produced posteriorly. (10) Clypeal surface broadly rounded, not flattened or depressed. Labrum as in Figure 535; (24) distal process absent; (25) basal area rounded medially, not depressed; (26) basal lateral depressions absent. (30) Mandible very short, not reaching opposing clypeal angle. (53) Clypeus weakly granulate, shiny; (54) punctation nearly uniform throughout, punctures separated by 1-2 times their width. (68) Clypeal maculation absent. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figures 203;

FIGURES 538-543.—Lasioglossum olympiae, male: 538, genitalia, ventral view; 539, same, dorsal view; 540, same, lateral view; 541, volsella; 542, gonostylus, 543, sterna VII-VIIII.

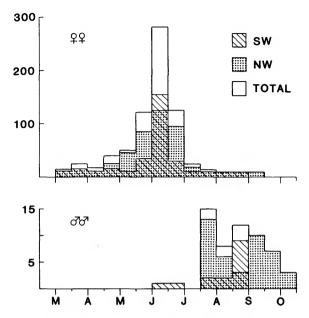

FIGURE 544.—Lasioglossum olympiae flight records.

(82) posterior half of sternum IV with dense, conspicuous band of adpressed hairs; (83) sternum V with a unique median, longitudinal patch of short, dense hairs; posterior sternal edge with short lateral hair fringes.

Terminalia: Sterna VII-VIII as in Figure 543; (84) unlike other species, sternum VII relatively large, median process broad; sternum VIII without median process, disc conspicuously broad. Genitalia in Figures 538–542; (86) gonobase short; (87) gonostylus short, broadly rounded; (89) retrorse membranous lobe extremely reduced, slender; (90) volsella with lateral flange but lacking prominent lobe.

FLIGHT RECORDS (Figure 544).—Lasioglossum olympiae females have been collected from March through early September, with 78% of the records from May and June, with a peak in early June. The one female collected in September was taken in Benton County, Oregon. The one female record from October was from Santa Clara County, California.

Most male specimens have been collected in late July through August, with records ranging from June to early October. All of the 17 records

from September were specimens collected in Oregon and British Columbia. The three males collected in October were from Latah County, Idaho; the two collected in June were from Alameda and Marin counties, California.

FLOWER RECORDS.—The flower records for *L. olympiae* are highly influenced by a large series of females (113 specimens) collected by E.G. Linsley and A.J. Walz in Mariposa County, California, June 1942. All of these females were taken from *Eriogonum* (none had pollen loads).

Summary: Females (204): Polygonaceae 52%; Rosaceae 13%. Males (10): Compositae 100%. Total: 214 in 15 families, 23 genera as follows:

Brassica 29; \*Ceanothus 8(2)9; Crataegus 19; \*Downingia 2(1)9; Eriogonum 1099; \*Eschscholtzia 2(1)9; \*Heracleum 12(4)9; Lasthenia 39; Layia 19; \*Limnanthes 8(1)9; Orthocarpus 29; \*Phacelia 2(2)9; Potentilla 49; Ranunculus 99; Rosa 89; Rubus 89; Salix 49; \*Sisyrinchium 1(1)9; Solidago 96; Spiraea 79; Taraxacum 19; Trifolium 79; Veronica 39.

#### 30. Lasioglossum orphnaeum, new species

FIGURES 43, 300, 545-553

TYPE MATERIAL.—The female holotype is in the Snow Museum, University of Kansas, Lawrence. It is in excellent condition and is labeled MEXICO Puebla Apulco (N. of Zacapoaxtla) 4700 ft. 19 June 1961 U. Kans. Mex. Exped./HOLOTYPE Lasioglos-

sum orphnaeum R.J. McGinley [red label].

The one male paratype is in the University of Kansas collection and six female paratypes are deposited in the Michigan State University collection in East Lansing (the paratypes are listed in the "Specimens Examined" section).

ETYMOLOGY.—The specific epithet is derived from the Greek *orphnos* (dark, dusky), and alludes to the dark-brown mesoscutal hairs characteristic of this species.

DISTRIBUTION (Figure 300).—Lasioglossum orphaneum is presently known from only seven females and one male from the Mexican states of Puebla and Veracruz.

DIAGNOSIS.—Females of L. orphnaeum are the only Mexican Lasioglossum having a strongly striate dorsal propodeal surface (Figure 547). The propodeum of L. perscabrum is highly sculptured but reticulate (Figure 599), not striate. Like L. perscabrum, the mesoscutal punctuation is coarse, nearly contiguous and becomes scabrous along the anterior edge (Figure 548) and the pronotal lateral angle is sharply projecting. Unlike L. perscabrum, the mesoscutal hairs of L. orphnaeum are dark brown (found elsewhere only in L. eickworti and L. katyae, which differ from L. orphnaeum in lacking the strongly sculptured propodeal surface). The pronotal lateral carina appears complete, only obscurely notched by an oblique lateral sulcus (Figure 549).

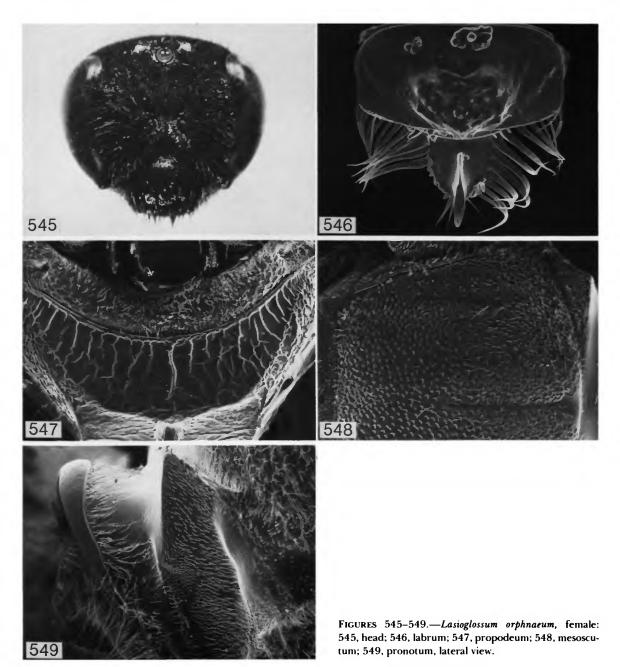

Lasioglossum citerius, known only from the unique holotype female, which lacks locality data, is probably a Mexican species (see "Distribution" section for L. citerius). It shares with L. orphnaeum the dark mesoscutal hairs, the striate dorsal propodeal surface, and the sharply projecting pronotal angles. Lasioglossum citerius differs from L. orphnaeum in having the anterior median edge of the mesoscutum strongly elevated and bilobed (moderately elevated and weakly bilobed in L. orphnaeum), having large, widely separated mesoscutal punctures posteriorly (Figure 336; compare with Figure 548), and by having a broadly interrupted pronotal lateral carina with the lower portion of the carina broadly rounded and inconspicuous (similar to that of L. pacificum, Figure 12; pronotal carina sharply edged, nearly complete in L. orphnaeum, Figure 549).

The propodeal sculpturing of the one known *L. orphnaeum* male is similar to that of the female but has fewer striae. The mesoscutal hairs of the male are not so dark as those of the female, and the pronotal lateral carina is conspicuously complete and sharply edged.

DESCRIPTION.—FEMALE: (1) Length 7.8–9.3 mm ( $\bar{x} = 8.3$ , n = 6); (2) wing length 2.3–2.4 mm ( $\bar{x} = 2.4$ , n = 6); (3) abdominal width 2.5–2.8 mm ( $\bar{x} = 2.6$ , n = 6).

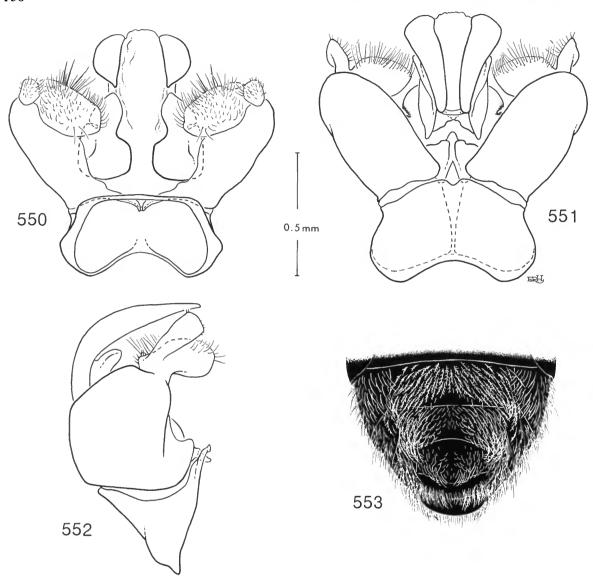

Structure: (4) Head short (Figure 545; length/width ratio 0.83-0.91,  $\bar{x}=0.88$ , n=6). (7) Supraclypeal area evenly rounded with well-developed frontal carina dorsally, (8) area weakly protuberant. (9) Clypeus projecting approximately 0.68 of its length below lower margin of eyes; (11) surface with obscure median longitudinal sulcation. (14) Distance between lateral ocelli slightly exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 546; (27) distal keel moderately narrow, lateral edges bowed; (28) distal lateral projections absent; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle forming sharply projecting right angle; (33) pronotal lateral ridge

nearly complete, obscurely notched by oblique lateral sulcus (similar to *L. perscabrum*); (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately

elevated from pronotum. (40) Dorsal surface of propodeum about 0.80 the length of scutellum and about 1.5 times the length of metanotum, (41) depressed centrally, (42) posterior margin

FIGURES 550-553.—Lasinglossum orphnaeum, male: 550, genitalia, ventral view, 551; same, dorsal view; 552, same, lateral view; 553, sternal vestiture.

rounded; (43) propodeal triangle defined medially by a low V-shaped elevation, laterally by distinct carinate rims; (44) lateral carinae well developed, extending nearly to dorsal surface. (45) Tibial spur as in Figure 43.

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face shiny, (48) densely and

uniformly punctate between ocelli and antennae punctures contiguous. (51) Supraclypeal area obscurely granulate, shiny; (52) punctation sparse. (53) Clypeus granulate basally, apical two-thirds polished; (54) punctures obscure basally, sparse apically, separated by 1–3 times their width. (56) Mesoscutum shiny; (57) punctation as in Figure 548, punctures coarse, contiguous laterally, sep-

arated by their width centrally, surface conspicuously scabrous anteriorly. (58) Scutellum with moderately sparse punctation adjacent to median line, punctures 2–3 times their width apart. (63) Dorsal surface of propodeum (Figure 547) strongly striate basally, posterior half rugose, median stria very well developed; (64) surface smooth, not alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane mostly hyaline, obscurely infuscated apically.

Vestiture: (74) Pubescence of head white on gena and near antennae, becoming brown on vertex. (75) Pubescence of mesoscutum, scutellum dark brown, hairs on metanotum, propodeum and mesopleuron white; (76) mesoscutal hairs moderately dense, conspicuously plumose. (77) Hind tibial hairs concolorous, brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I. (81) Unlike most species, basal hair hands narrow, covering at most basal 0.25 of terga.

MALE: Similar to female except as follows: (1) length 7.0 mm (n = 1); (2) wing length 2.2 mm (n = 1); (3) abdominal width 2.0 mm (n = 1). (4) Head short, length/width ratio 0.90 (n = I). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (10) Clypeal surface noticeably depressed ventrally. (24) Labral distal process weakly developed, broadly rounded; (25) basal area only faintly depressed medially; (26) basal lateral depressions well developed. (30) Mandible moderately elongate, reaching slightly beyond opposing clypeal angle. (53) Clypeus granulate, shiny; (54) punctation nearly uniform throughout, punctures larger and slightly less dense towards apical edge, absent in apical median depression. (68) Clypeal maculation absent. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 553; (82) hairs on sternum IV moderately short, sub-erect medially, directed laterally and becoming

elongate near lateral edge of sternum; (83) vestiture of sternum V similar to that of sternum IV but with lateral elongate hairs noticeably curled.

Terminalia: Sterna VII-VIII were not available for study. Genitalia as in Figures 550-552; (86) gonobase moderately elongate; (87) gonostylus elongate, gradually increasing in width to bluntly rounded apex; (89) retrorse membranous lobe very short, bulbous; (90) volsella with weakly developed lateral lobe.

FLIGHT RECORDS.—Six of the seven known *L. orphnaeum* females were collected in early August. The other female and the one known male were taken in late June.

Specimens Examined.—Holotype and seven paratypes (79, 18).

## 31. Lasioglossum pacificum (Cockerell)

FIGURES 12, 44, 554-568

Halictus pacificus Cockerell, 1898c:50-51 [female, misidentified male, key].—Vachal, 1904:472 [female].—Crawford, 1906:301 [locality record].

Lasioglossum pacificum.—Michener, 1951:1107 [Nearctic catalog].—Linsley and MacSwain, 1959:22 [flight records, association with Ranunculus].—Moldenke and Neff, 1974:54 [locality and flower records].—Hurd, 1979:1957 [Nearctic catalog].

TYPE MATERIAL.—In his original description of *Halictus pacificus*, Cockerell did not designate a holotype. The lectotype female, designated herein, is labeled

HOLOTYPE [on red label/Olympia [Thurston County], Wash.[ington]/6 [June] 24 [18]95 [handwritten in pencil]/ H.[alictus] pacificus. Ckll. [Cockerell] n. sp. [new species] [handwritten by Cockerell/LECTOTYPE Halictus pacificus Cockerell des.[ignated by] McGinley [on red label].

The specimen, deposited in the California Academy of Sciences in San Francisco, has many body hairs soiled or matted but otherwise is in good condition.

Cockerell mentions that the male of *H. pacificus* has the "apical portion of clypeus yellow" and the "hind tibiae at both ends, and all the tarsi, yellow," which is clearly a misassociation, as both the clypeus and tarsi of *L. pacificum* are never yellow. The male that Cockerell describes is possibly that of *L. titusi*, which was described by Crawford, four years later in 1902.

DISTRIBUTION (Figure 554).—Lasioglossum pacificum is presently known from the extreme southwestern corner of British Columbia, including Vancouver Island and south through the coastal and subcoastal areas of Oregon, Washington, and California to Santa Barbara County.

DIAGNOSIS.—The strongly and regularly striate propodeal dorsal surface (Figure 559) will distinguish Lasioglossum pacificum from other Lasioglossum species except L. leucozonium, L. zonulum, L. sisymbrii, and L. timberlakei. Lasioglossum leucozonium and L. zonulum differ in having relatively longer heads (Figures 492, 555, 734) and in having a conspicuously short propodeal dorsal surface, which is only slightly longer than the metanotum (Figures 496, 738; propodeal surface much longer than the metanotum in L. pacificum and most other species). Of the two species, only L. zonulum occurs sympatrically with L. pacificum and is further differentiated by its sharply pointed lateral pronotal angles (Figure 141; pronotal angles broadly obtuse in L. pacificum). The unique first tergal basal hair band (Figure 132) and the pale, translucent tegulae will differentiate L. sisymbrii. Lasioglossum olympiae is very similar but can be distinguished by its sharply truncated posterior propodeal margin (Figure 536; slightly bowed posteriad in L. pacificum, Figure 559), slightly different head shape (Figure 532 vs. Figure 555) and the smooth, relatively polished area immediately dorso-anteriad of the middle coxa (Figure 146; area striolate and dull in L. pacificum, Figure 147). The most similar species to L. pacificum is L. timberlakei (especially the dark form), which can be differentiated by its weak, obscure mesoscutal punc-

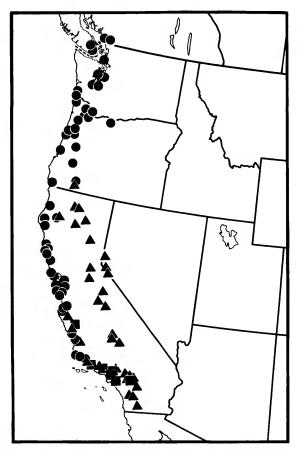

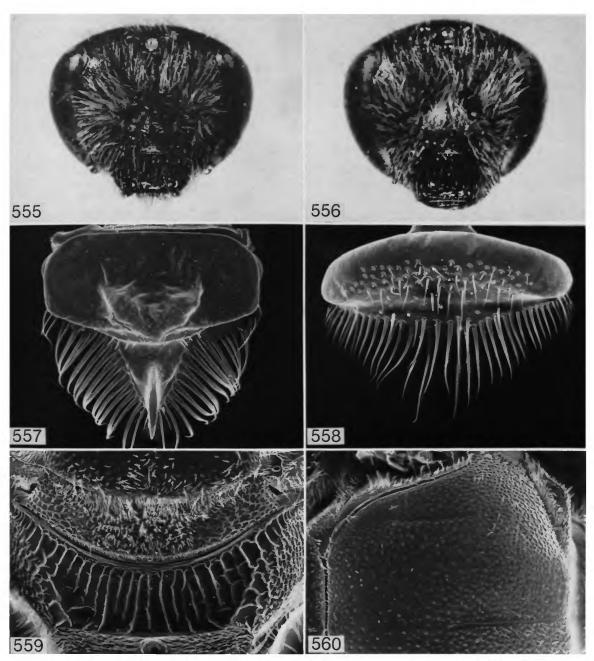

FIGURE 554.—Distribution of Lasioglossum pacificum (circle), L. timberlakei light form (triangle), and L. timberlakei dark form (square).

tation (Figure 622 vs. Figure 560) and the short, dense pubescence along the posterolateral margin of the mesoscutum (hairs elongate in *L. pacificum*).

The presence of elongate hair tufts on the lateral edges of sternum V (Figure 561) will differentiate the males of L. pacificum from those of other Lasioglossum species except L. sisymbrii and L. timberlakei. These species also share the lack of a clypeal maculation and have the dorsal propodeal surface strongly striate to rugose. Lasioglossum sisymbrii males have a basal white hair band on tergum I as in Figure 132 (absent in L. pacificum) and pale, translucent tegulae (dark

NUMBER 429

FIGURES 555-560.—Lasioglossum pacificum: 555, female head; 556, male head; 557, female labrum; 558, male labrum; 559, female propodeum; 560, female mesoscutum.

brown in *L. pacificum*). Lasioglossum pacificum males differ from those of *L. timberlakei* in having well-developed mesoscutal punctation (punctures sparse and obscurely developed in the latter two species). Furthermore, the vestiture of sternum V of both species differs slightly as illustrated in Figures 561, 562.

DESCRIPTION.—FEMALE: (1) Length 8.4–10.8 mm ( $\bar{x} = 9.7$ , n= 15); (2) wing length 2.4–2.8 mm ( $\bar{x} = 2.7$ , n = 15); (3) abdominal width 2.8–3.4 mm ( $\bar{x} = 3.2$ , n = 15).

Structure: (4) Head short (Figure 555; length/width ratio 0.79-0.89,  $\bar{x}=0.85$ , n=15). (7) Supraclypeal area evenly rounded. (8) weakly protuberant. (9) Clypeus projecting approximately 0.70 of its length below lower margin of eyes; (10) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 557; (27) distal keel narrow in frontal view, lateral edges slightly bowed; (28) distal lateral projections virtually absent, evident as obscure swellings; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip rounded, not bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.65 the length of scutellum and subequal to metanotum in length, (41) not depressed centrally, (42) posterior margin truncated (slightly bowed posteriad); (43) propodeal triangle weakly defined laterally; (44) lateral carinae completely encircling posterior surface. (45) Tibial spur as in Figure 44.

(46) Lateral edge of metasomal tergum 11 very weakly sinuate, posterior two-thirds shallowly concave.

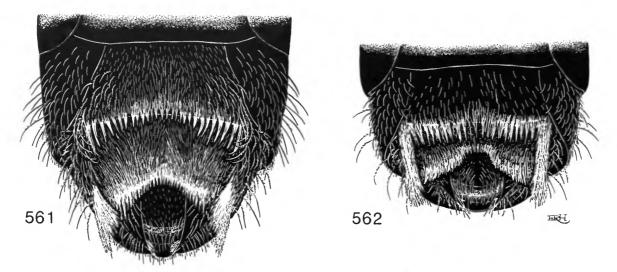

Sculpture: (47) Face shiny, (48) densely punctuate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area extremely granulate; (52)

punctures separated by their width laterally, slightly less dense centrally. (53) Clypeus granulate basally and medially to apex, apicolateral areas polished; (54) punctures obscure, separated by less than their width basally, becoming well defined and less dense apically. (56) Mesoscutum shiny; (57) punctation as in Figure 560, punctures 1-2 times their width apart laterally and anteriorly, 2-4 times their width apart centrally. (58) Scutellum with conspicuous impunctate areas adjacent to median line. (63) Dorsal surface of propodeum (Figure 559) strongly and completely striate to porcate, striae evenly spaced with very few obscure transverse rugulae; (64) surface smooth, not alveolated. (65) Metasomal tergum 1 shiny; (66) punctation extremely fine, sparse posteriorly, punctures 2-3 times their width apart, punctures scattered anteriorly with large impunctate areas.

Coloration: (71) Wing membrane nearly hyaline, very lightly pigmented.

Vestiture: (74) Pubescence of head golden. (75) Pubescence of thorax golden; (76) mesoscutal hairs moderately dense, very conspicuously plumose. (77) Hind tibial hairs concolorous, golden. (78) Anterior hairs of metasomal tergum 1 and (79) basal hair bands of terga 1I–IV yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum 1. (81) Unlike other species, basal hair band of tergum 11 interrupted medially.

MALE: Similar to female except as follows: (1) length 7.3–9.0 mm ( $\bar{x}=8.0$ , n=15); (2) wing length 2.1–2.4 mm ( $\bar{x}=2.3$ , n=15); (3) abdominal width 2.0–2.6 mm ( $\bar{x}=2.3$ , n=15). (4) Head as in Figure 556 (length/width ratio 0.83–0.92,  $\bar{x}=0.87$ , n=15). (5) Gena subequal to eye in width, (6) rounded, not produced posteriorly. (10) Clypeal surface broadly rounded, not flattened or depressed. Labrum as in Figure 558; (24) distal process very weakly developed, broadly rounded; (25) basal area rounded medially, not depressed; (26) basal lateral depressions absent. (30) Mandible very short, not reaching opposing clypeal angle. (53) Clypeus weakly granulate, shiny; (54) punctation nearly uniform

FIGURES 561, 562.—Male sternal vestiture: 561, L. pacificum; 562, L. timberlakei.

throughout, punctures separated by 1–2 times their width. (68) Clypeal maculation absent. (69) Flagellum entirely dark to pale yellowish orange ventrally and contrasting with dark dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 561; (82) hairs on sternum IV short, adpressed, with noticeable hair fringe on posterior sternal edge; (83) sternum V with rounded hair fringe on posterior sternal edge, hairs becoming elongate laterally, forming conspicuous lateral tufts.

Terminalia: Sterna VII-VIII as in Figure 567; (85) sternum VIII without median process, distal edge of disc sharply truncated. Genitalia as in Figures 563-566; (86) gonobase moderately elongate; (87) gonostylus moderately elongate, robust, bluntly rounded; (89) retrorse membranous lobe extremely reduced, slender; (90) volsella with weakly developed lateral flange but lacking prominent lateral lobe.

FLIGHT RECORDS (Figure 568).—Lasioglossum pacificum females have been collected from February to late November, with most records from late May and June. Male records range from late June to early October, with a southwestern peak in early August and a northwestern peak in early September.

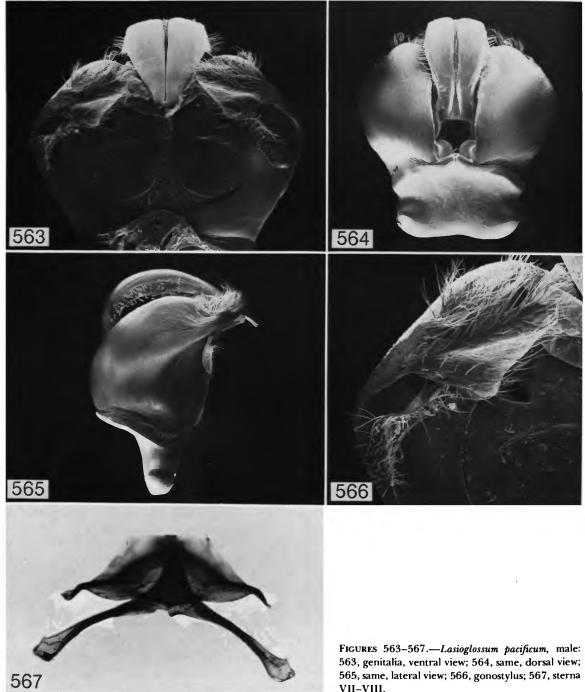

FLOWER RECORDS.—Females (41): Ranunculaceae 15%; Cruciferae 12.5%; Compositae 12.5%; Scrophulariaceae 12.5%; Umbelliferae 12.5%. Males (7): Compositae 88%; Convolvulaceae 12%. Total: 48 in 14 families, 22 genera as follows:

Achillea 19, 56; Anaphalis 19, 206; Angelica 29; Brassica 59; Chrysanthemum 19; Cichorium 19; Cicuta 19; Convolvulus 16; Cornus 19; \*Heracleum 2(1)9; Iris 19; Myosotis 19; \*Orthocarpus 4(4)9; Poa 19; \*Potentilla 1(1)9; \*Ranunculus 6(1)9; \*Rhodoendron 4(4)9; Rubus 19; \*Salix 4(1)9; Scrophularia 19; Stellaria 19; Taraxacum 19.

# 32. Lasioglossum pallicorne (Vachal)

FIGURES 45, 569-581

Halictus pallicornis Vachal, 1904:477 [male].—Cockerell, 1905a:90 [key].

Lasioglossum pallicorne.—Moure and Hurd, 1986:63 [catalog].

TYPE MATERIAL.—The male holotype, deposited in the Paris Museum (MNHNP), is labeled

Mexico t.f./MUSEUM PARIS COLL. O.SICHEL 1867/ HOLOTYPE [handwritten on red label]/H.[alictus]& pallicornis Vach.[al] handwritten by Vachal?]/Halictus pallicornis Vach. [recent label].

The specimen is in good condition except for missing the last 10 flagellomeres of the left an-

tenna and having the body hairs soiled. However, the diagnostic hair pattern of sternum V (Figure 576) is clearly visible.

DISTRIBUTION (Figure 569).—The known distribution of *L. pallicorne* is similar to that of *L. transvorsum* in being limited to a small area around Mexico City from Michoacan to Veracruz. The species is presently known from 16 females and 34 males.

DIAGNOSIS.—The structure of the metasomal acarinarium (Figure 578) makes the females of L. pallicorne among the most distinctive of New World Lasioglossum. The acarinarium is a heartshaped, bilateral depression enclosed laterally by a thick canopy of fringe hairs. The area immediately posteriad of the acarinarium is conspicuously hairless (this bald area is also noticeable in the males). The acarinaria of all other mitecarrying Lasioglossum are never heart-shaped and have only lateral hair fringes that never form a canopy enclosing the acarinarial surface. Other characters helpful in recognizing females of L. pallicorne are the well-developed, elevated posterior rim of the relatively elongate propodeal dorsal surface (Figure 574), the complete pronotal lateral ridge (Figure 577), and the short head (Figure 570).

Males of *L. pallicorne* are unique in having conspicuously elongate and curled hairs on the extreme lateral edges of sternum V (Figure 576). Like the females the pronotal lateral ridge is complete and there is an extensive hairless area across the anterior surface of the first metasomal tergum. The propodeal dorsal surface is elongate but usually lacks the elevated posterior rim that is found in the females.

DESCRIPTION.—FEMALE: (1) Length 6.8–8.7 mm ( $\bar{x} = 7.8$ , n = 12); (2) wing length 2.1–2.4 mm ( $\bar{x} = 2.3$ , n = 12); (3) abdominal width 2.2–2.8 mm ( $\bar{x} = 2.5$ , n = 12).

Structure: (4) Head short (Figure 570); length/width ratio 0.78-0.96,  $\bar{x}=0.87$ , n=12. (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.76 of its length below lower margin of eyes; (11) surface without median longi-

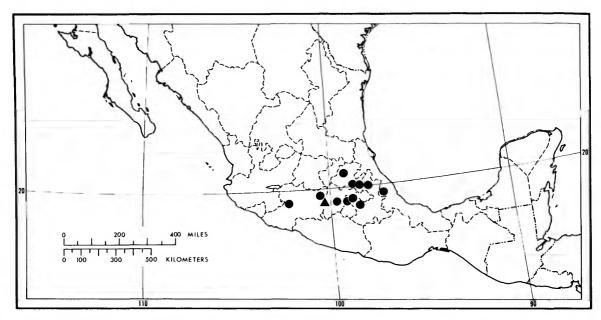

FIGURE 569.—Distribution of Lasioglossum pallicorne (circle) and L. parkeri (triangle).

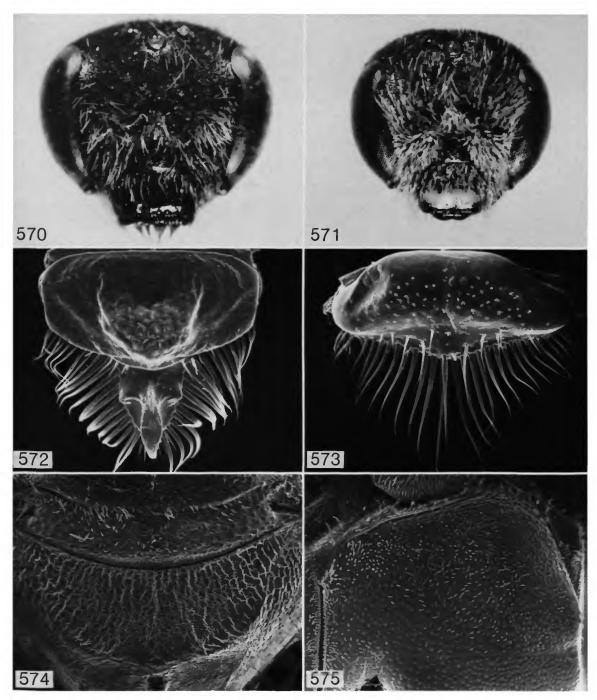

tudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 572; (27) distal keel broad in frontal view, somewhat spoon-shaped, with conspicuous basal median groove; (28) distal lateral projections well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge complete, slightly notched by oblique lateral sulcus but not distinctly interrupted; (34) lower portion of lateral ridge sharply edged near oblique sulcus, becoming narrowly rounded ventrally. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum very elongate, about 0.95 the length of scutellum and about 1.7 times the length of metanotum, (41) depressed centrally, (42) posterior margin rounded; (43) propodeal triangle well defined medially by a sharply edged V-shaped elevation with conspicuous lateral rims, becoming faint towards metanotum; (44) lateral carinae extend-

ing at most one-third the length of posterior surface. (45) Tibial spur as in Figure 45.

(46) Lateral edge of metasomal tergum II only faintly sinuate, virtually straight.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) punctation extremely sparse with few, scattered punctures. (53) Clypeus strongly granulate basally, apical twothirds moderately polished; (54) punctures obscure basally, separated by their width over apical half. (56) Mesoscutum shiny; (57) punctation as in Figure 575, punctures dense laterally and anteriorly, punctures separated by less than their width, becoming less dense centrally, punctures separated by 1-2 times their width. (58) Scutellar punctation nearly uniform, only slightly less punctate adjacent to median line with punctures 1-2 times their width apart. (63) Dorsal surface of propodeum (Figure 574) mostly smooth centrally, basal one-third, lateral areas and posterior edge ruguloso-striolate; (64) surface extensively alveolated. (65) Metasomal tergum I moderately

FIGURES 570-575.—Lasioglossum pallicorne: 570, female head; 571, male head; 572, female labrum; 573, male labrum; 574, female propodeum; 575, female mesoscutum.

shiny; (66) punctation fine, extremely dense, punctures nearly contiguous; surface impunctate and noticeably granulate posteriad to acarinarial hair fringes.

Coloration: (7 I) Wing membrane pale yellowish brown.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax yellowish brown; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color weakly differentiated, most hairs pale yellowish brown, dorsal hairs light brown. (78) Anterior hairs of metasomal tergum I pale yellowish brown, (79) basal hair bands of terga II-IV white. (80) Acarinarium present (Figures 162, 578), unlike other species a bilaterally depressed, heart-shaped, glabrous area, surrounded and enclosed laterally by elongate fringe hairs; dorsal opening of acarinarium extremely narrow, at most 0.25 the width of lateral hair fringe; with conspicuous hairless area posteriad to fringe hairs.

MALE: Similar to female except as follows: (I) length 6.2-7.9 mm ( $\bar{x} = 2.0$ , n = 15); (2) wing length I.7-2.3 mm ( $\bar{x} = 2.0$ , n = 15), (3) abdominal width I.7-2.I ( $\bar{x} = I.9$ , n = I5). (4) Head as in Figure 57I (length/width ratio 0.86-0.95,  $\bar{x}$ = 0.90, n = 15). (5) Gena slightly wider than eye; (6) moderately produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 573; (24) distal process weakly developed, rounded; (25) basal area moderately depressed medially; (26) basal lateral depressions conspicuously developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed, nearly contiguous basally, larger and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum entirely dark or only slightly paler ventrally than on dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 576; (82) hairs on sternum IV moderately elongate medially, directed laterally from midline, gradually becoming elongate on lateral edge of sternum; (83) vestiture of sternum V similar to that

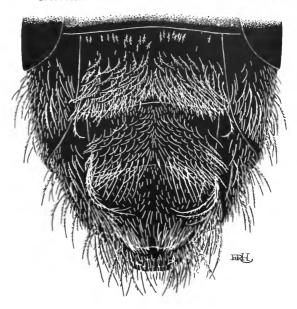

FIGURE 576.—Lasioglossum pallicorne, male sternal vestiture.

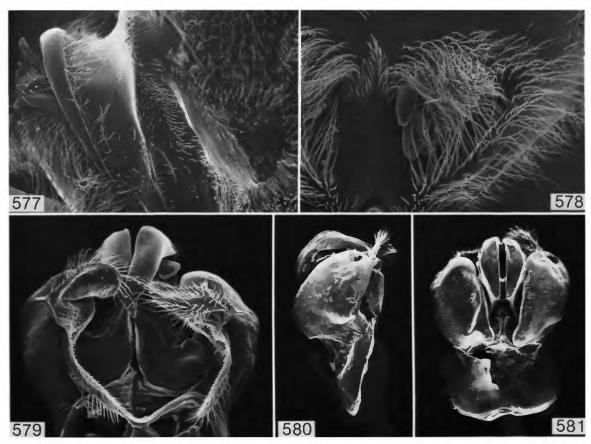

of sternum IV but with two to five conspicuously elongate and curled hairs on posterolateral sternal edge.

Terminalia: (85) Sternum VIII with moderately elongate, slender median process, rounded apically. Genitalia as in Figures 579–58I; (86) gonobase elongate; (87) gonostylus elongate, expanding to conspicuous bulbous apex; (89) retrorse membranous lobe extremely slender; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS.—Lasinglossum pallicorne females have been collected from late June through August. Most male records are from May, with additional records from June and July. Little can be said of *L. pallicorne* flight activity, because of the limited number of specimens currently available for study.

FLOWER RECORDS.—One female from the state of Mexico taken on *Heterotheca chrysopsidis* and another female from Puebla taken on *Heterotheca* sp.

MITE ASSOCIATES.—As described in the diagnosis and description (character 80), the acarinarium of the *L. pallicorne* female is the most

FIGURES 577-581.—Lasinglossum pallicorne: 577, female pronotum, lateral view; 578, female acarinarium at base of tergum 1; 579, male genitalia, ventral view; 580, same, lateral view; 581, same, dorsal view.

elaborate of all known Lasioglossum species (Figure 578). Of the examined females, 81.2% had hypopodes in their acarinarium. Although the sample is limited at present, an unusually high number of the males (60.6%) carried mites. Unlike all other Lasioglossum species, mites on L. pallicorne males form conspicuously dense, shingled rows and are found exclusively on the genae. The regularity of positioning on the males, the relatively high number of males carrying hypopodes, and the conspicuous development of the female acarinarium suggest a very close association between L. pallicorne and its phoretic mites. Specimens Examined.—49 (162, 333).

#### 33. Lasioglossum parkeri, new species

FIGURES 569, 582

TYPE MATERIAL.—The female holotype of *L.* parkeri is deposited in the University of California at Davis and is labeled

10 mi. east Zitacuaro Mich.[oacan] MEX.[ico] 111 [Mar] 26 1962/F.D. Parker L.A. Stange Collectors/HOLOTYPE Lasioglossum parkeri R.J. McGinley [red label].

When received, the abdomen was loosely attached to the thorax and is now contained in a micro-vial pinned with the specimen (gluing the abdomen may have obscured details of the diagnostic acarinarium). The specimen is otherwise in excellent condition.

ETYMOLOGY.—This species is named after F.D. Parker (Bee Biology and Systematics Laboratory and Utah State University), who along with L.A. Stange (Florida State Collection of Arthropods, Gainesville) collected the unique female holotype.

DISTRIBUTION (Figure 569).—This species is presently known only from the type-locality: 10 miles east of Zitacuaro, Michoacan (on the border of the state of Mexico).

DIAGNOSIS.—The female of this species can be recognized by its distinctive acarinarium (at the base of abdominal tergum I), which is a concave, circular, glabrous surface completely surrounded by erect fringe hairs (Figure 582). The only other New World Lasioglossum with an acarinarium completely surrounded by fringe hairs is L. coriaceum, a species from the eastern United States. The fringe hairs of L. coriaceum are adpressed, not erect (Figure 72). Lasioglossum parkeri appears to be related to the Mexican L. pallicorne as evidenced by the unusual dorsal propodeal

FIGURE 582.—Lasioglossum parkeri, female acarinarium at base of tergum 1.

surface that is surrounded by conspicuously elevated lateral rims (as in Figure 574). Like *L. pallicorne*, the propodeal dorsal surface is smooth (conspicuously alveolated) over its posterior half, the head is short (similar to Figure 570), and the mesoscutal punctation is dense but not quite granuloso-punctate (as in Figure 575). *Lasioglossum pallicorne* is easily differentiated from *L. parkeri* by its bilaterally depressed, heart-shaped acarinarium (Figure 578).

DESCRIPTION.—FEMALE: (1) Length 8.8 mm (n = 1); (2) wing length 2.5 mm; (3) abdominal width 2.7 mm.

Structure: (4) Head short (similar to that of L. pallicorne, Figure 570); length/width ratio 0.83. (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.67 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli slightly shorter than distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum similar to that of L. pallicorne (Figure 572) but (27) distal keel not so broad, basal median groove not so conspicuous, (28) distal lateral projections small, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge appearing complete, only

slightly notched by oblique lateral sulcus but not distinctly interrupted; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum very elongate, about 0.92 the length of scutellum and about 1.6 times the length of metanotum, (41) depressed centrally, (42) posterior margin rounded; (43) propodeal triangle well defined medially by a sharply edged V-shaped elevation with conspicuous lateral rims, becoming faint towards metanotum; (44) lateral carinae extending at most one-third the length of posterior surface. (45) Tibial spur similar to that of *L. pallicorne* (Figure 45).

(46) Lateral edge of metasomal tergum II only faintly sinuate, virtually straight.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area moderately granulate; (52) punctation extremely sparse with few, scattered punctures. (53) Clypeus moderately granulate basally, apical twothirds moderately polished; (54) punctures obscure basally, separated by their width over apical half. (56) Mesoscutum shiny; (57) punctation similar to that in Figure 575, punctures dense, nearly contiguous laterally and anteriorly, punctures becoming slightly less dense centrally, punctures separated by their width or slightly less. (58) Scutellum largely impunctate centrally. (63) Dorsal surface of propodeum similar to that of L. pallicorne (Figure 574), ruguloso-striolate on basal half, smooth on posterior half; (64) surface extensively alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous; surface nearly glabrous posteriad to acarinarial hair fringes (Figure 582).

Coloration: (71) Wing membrane pale yellowish brown.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax yellowish brown; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, most hairs on dorsal surface

brown, hairs yellowish brown on ventral and lateral surfaces. (78) Anterior hairs of metasomal tergum I pale yellowish brown, (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium present (Figure 582), a concave, circular, glabrous area, completely surrounded by erect fringe hairs; area posteriad of acarinarium conspicuously hairless.

MITE ASSOCIATES.—The one female available for study had her acarinarium partially filled with histiostomatid hypopodes.

SPECIMENS EXAMINED.—One holotype female, Zitacuaro, 10 mi E, Michoacan, Mexico, 26 Mar 1962, F.D. Parker and L.A. Stange (UCD).

## 34. Lasioglossum pavonotum (Cockerell)

FIGURES 47, 583-597

Halictus pavonotus Cockerell, 1925:188 [female, male].
 Lasioglossum pavonotum.—Michener, 1951:1107 [Nearctic catalog].—Moldenke and Neff, 1974:55 [locality and flower records].—Hurd, 1979:1957 [Nearctic catalog].

Type Material.—The female holotype of *Halictus pavonotus* is in the California Academy of Sciences, San Francisco. It is in excellent condition and is labeled

San Francisco Cal.[ifornia] 111-[March] 30-1913/EC Van Dyke Collectir [sic]/Halictus pavonotus Ckll. [Cockerell] TYPE [handwritten by Cockerell]/California Academy of Sciences Type No. 1650.

DISTRIBUTION (Figure 583).—Lasioglossum pavonotum is known only from sandy habitats immediately along the Pacific coastline and sandbanks along the Sacramento River. It is presently known only from Pacific County, Washington, south to Orange County, California, including San Miguel Island.

DIAGNOSIS.—Both sexes of Lasioglossum pavonotum are the only metallic blue-green bees of this genus in the New World. All other Lasioglossum species in the New World are dark brown to black, never metallic.

DESCRIPTION.—FEMALE: (1) Length 7.3–9.1 mm ( $\bar{x} = 8.2$ , n = 15); (2) wing length 1.9–2.8

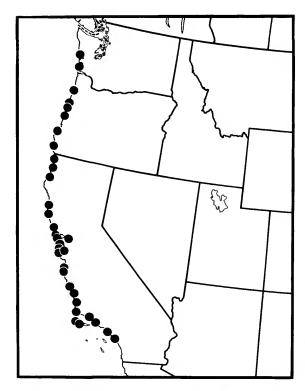

FIGURE 583.—Distribution of Lasinglossum pavonotum.

mm ( $\bar{x}$  = 2.2, n = 15); (3) abdominal width 2.2–3.0 mm ( $\bar{x}$  = 2.7, n = 15).

Structure: (4) Head elongate (Figure 584; length/width ratio 0.84-0.96,  $\bar{x}=0.92$ , n=15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.93 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly longer than 2 along dorsal surface. Labrum as in Figure 586; (27) distal keel narrow in frontal view, nearly parallel-sided; (28) distal lateral projections well developed, rounded; (29) fimbrial setae acutely pointed; unlike other species, basal elevation of labrum not developed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower

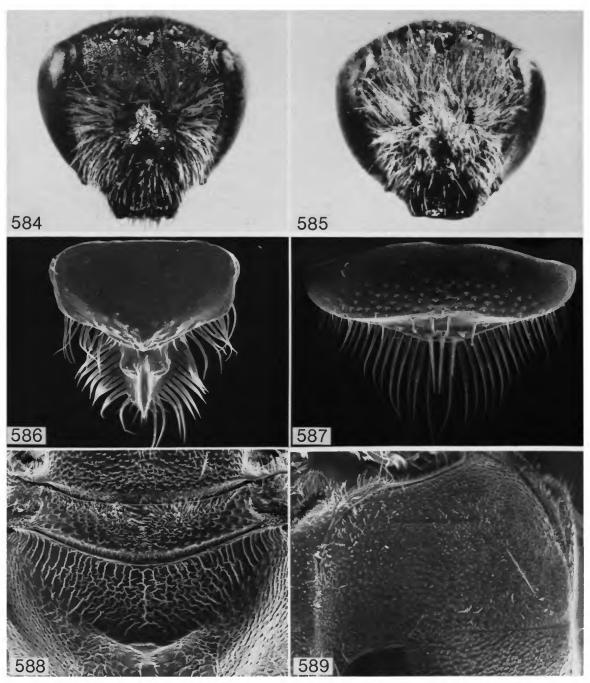

portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.75 the length of scutellum and about 1.2 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined laterally, evident medially as a conspicuous, sharply edged V-shaped elevation with lateral rims, fading towards metanotum; (44) lateral carinae extending to or slightly beyond midpoint of posterior surface. (45) Tibial spur as in Figure 47.

(46) Lateral edge of metasomal tergum II broadly rounded with posterior half somewhat truncated.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming only slightly larger and less dense near antennae. (51) Supraclypeal area extremely granulate; (52) punctures separated by their width laterally, becoming less dense centrally. (53) Clypeus granulate basally, apical half weakly granulate, somewhat polished; (54) punctures obscure, becoming very sparse apically. (56) Mesoscutum shiny; (57) punctation as in Figure 589, punctation uniform, contiguous, becoming granuloso-punctate anteriorly. (58) Scutellum nearly uniformly punctate, punctures less dense than those of mesoscutum, separated by their width or slightly less. (63) Dorsal surface of propodeum (Figure 588) striolate to ruguloso-striolate laterally, becoming rugulose medially, striae and rugulae reaching posterior margin only laterally; (64) surface alveolated. (65) Metasomal tergum I shiny, granulate; (66) punctation extremely fine, obscure, moderately sparse posteriorly, punctures 1-2 times their width apart, surface impunctate centrally and anteriorly (forming weakly developed acarinarium, see species discussion).

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense, conspicuously plumose. (77) Hind tibial hair color very weakly differentiated, hairs mostly white, dorsal hairs light

FIGURES 584-589.—Lasioglossum pavonotum: 584, female head; 585, male head; 586, female labrum; 587, male labrum; 588, female propodeum; 589, female mesoscutum.

brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium not obviously developed (mites attach to impunctate median area of tergum I, base of tergum I with scattered elongate hairs as in non-mite-carrying species, Figure 591); metasoma highly unique in having lateral patches of adpressed, short, white hairs at anterior edges of tergum I (similar to basal hair band of *L. sisymbrii* but interrupted), apical edges of metasomal terga with short white hair fringe; basal hair bands of terga II–IV weakly defined, that of tergum IV nearly covering entire surface.

MALE: Similar to female except as follows: (1) length 6.7-8.4 mm ( $\bar{x} = 7.4$ , n = 15); (2) wing length 1.7-2.2 mm ( $\bar{x} = 1.9$ , n = 15); (3) abdominal width I.6-2.1 mm ( $\bar{x} = 1.9$ , n = 15). (4) Head as in Figure 585 (length/width ratio 0.86-0.95,  $\bar{x} = 0.91$ , n = 15). (5) Gena subequal to eye in width, (6) rounded, not produced posteriorly. (10) Clypeal surface with conspicuous median depression on ventral half. Labrum as in Figure 587; (24) distal process very weakly developed, rounded; (25) basal area rounded medially, not depressed; (26) basal lateral depressions absent. (30) Mandible very short, not quite reaching opposing clypeal angle. (53) Clypeus polished; (54) punctation nearly uniform throughout, punctures slightly less dense apically and on apical median depression. (68) Clypeal maculation absent. (69) Flagellum slightly paler on venter than on dark dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 590; (82) hairs on sternum IV adpressed, elongate, curling inward towards midline; (83) hairs on sternum V similar to those on sternum V but with median rosette of short hairs.

Terminalia: Sterna VII-VIII as in Figure 596; (85) sternum VIII without median process. Genitalia as in Figures 592–595; (86) gonobase moderately short; (87) gonostylus enormous, subequal in size to retrorse membranous lobe; (89) retrorse membranous lobe moderately slender, conspicuously hairy; (90) volsella with broadly rounded lateral lobe.

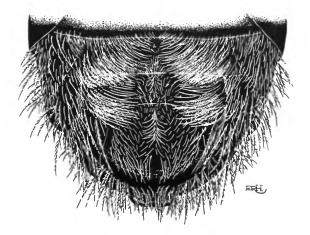

FIGURE 590.—Lasioglossum pavonotum, male sternal vesti-

FLIGHT RECORDS (Figure 597).—Lasioglossum pavonotum females have been collected from February to early November, with records from California peaking in April, whereas those from Oregon and Washington peak in early June. Male records peak in August but range from early March through October.

FLOWER RECORDS.—Females (65): Compositae 49%; Polygonaceae 18%; Leguminose 15%; Papaveraceae 9%. Males (21): Compositae 67%; Aizoaceae 14%; Hydrophyllaceae 14%. Total: 86 in six families, 13 genera as follows:

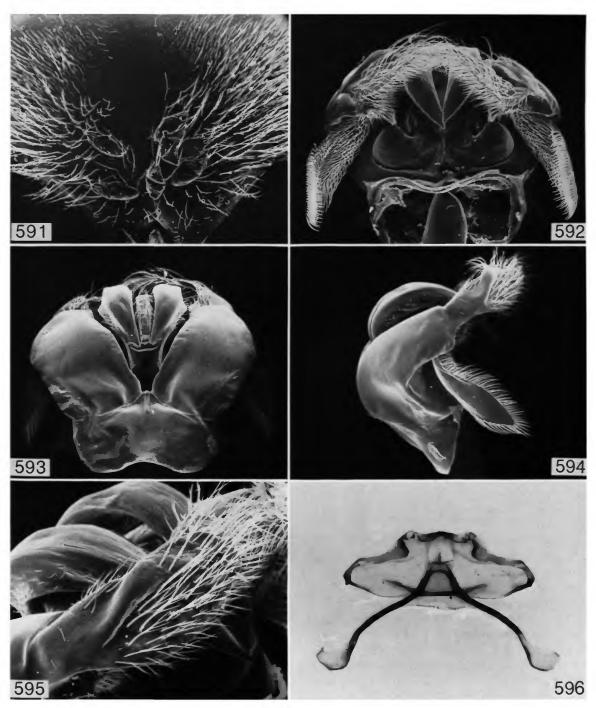

Achillea 29; \*Agoseris 5(3)9; Baccharis 1&; Eriogonum 129; \*Escholtzia 6(2)9, 1&; Grindelia 49, 13&; \*Hypochoeris 4(3)9; Layia 49; \*Lupinus 9(1)9; Malacothrix 13 9; Meliotus 19; Mesembryanthemum 19, 3&; Phacelia 49, 3&.

MITE ASSOCIATES.—The acarinarium of female *L. pavonotum* is very weakly developed, represented only by a glabrous median area of the anterior surface of metasomal tergum I (Figure 591). Only 10.4% of the females and 5.3% males examined in this study carried mites.

Specimens Examined.—845 (6192, 2268).

### 35. Lasioglossum perscabrum, new species

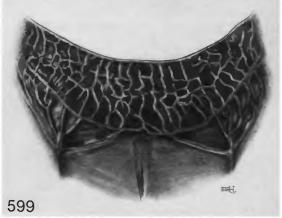

FIGURES 48, 300, 598, 599

TYPE MATERIAL.—The female holotype and two paratypes are deposited in the Snow Museum, University of Kansas. The holotype is labeled

MEXICO San Luis Potosi, 17 mi. E. Cd.[Ciudad del] Maiz, 3200 '[feet] 23 July 1962 U.[niversity] Kans.[as] Mex.[ican] Exped.[ition]/LASIOGLOSSUM det.[ermined by] G.C. Eickwort/HOLOTYPE Lasioglossum perscabrum R.J. McGinley [red label].

The holotype is in excellent condition.

FIGURES 598, 599.—Lasioglossum perscabrum, female: 598, labrum; 599, propodeum.

ETYMOLOGY.—The specific epithet is derived from the Latin per (very) plus scabrum (rough), a reference to the strongly reticulate dorsal propodeal surface (appearing scabrous through light microscope) that differentiates this species from all other known New World Lasioglossum.

DISTRIBUTION (Figure 300).—Lasioglossum perscabrum is known from only three females collected in 1954 and 1962 in the vicinity of Ciudad del Maiz, San Luis Potosi, Mexico.

DIAGNOSIS.—The entirely reticulate dorsal propodeal surface (Figure 599) will distinguish L. perscabrum from all other known Mexican Lasioglossum (the propodeal surface of L. orphnaeum is highly sculptured but is striate, not

reticulate, Figure 547). Like L. citerius and L. orphnaeum and no other Mexican Lasioglossum species, the mesoscutal punctation is coarse, nearly contiguous and becomes scabrous anteriorly (similar to Figure 548) and the pronotal lateral angle is a sharply projecting right angle. Lasioglossum perscabrum can further be differentiated from L. citerius and L. orphnaeum in that the latter two species have dark brown mesoscutal hairs (at most light brown in L. perscabrum). Other characters helpful in recognizing L. perscabrum, also shared with L. citerius and L. orphnaeum, are the short head (similar to Figure 545) and the absence of a metasomal acarinarium.

DESCRIPTION.—FEMALE: (1) Length 8.4–8.9 mm ( $\bar{x} = 8.6$ , n = 3); (2) wing length 2.2–2.4 mm ( $\bar{x} = 2.3$ , n = 3); (3) abdominal width 2.9–3.0 mm ( $\bar{x} = 2.9$ , n = 3).

Structure: (4) Head short (similar to Figure 548; length/width ratio 0.81-0.83,  $\bar{x}=0.82$ , n = 3). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.67 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 598; (27) distal keel moderately broad in frontal view, slightly widest basally; (28) distal lateral projections extremely well developed, conspicuously elongated and prong-like; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle forming sharply projecting right angle; (33) pronotal lateral ridge nearly complete, obscurely interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum elongate, about 0.94 the length of scutellum and about 1.5 times the length of metanotum, (41) not depressed centrally, (42) posterior margin sharply truncated; (43) propodeal triangle well defined by circular carina; (44) lateral carinae encircling posterior

surface, interrupted dorsally by V-shaped elevation. (45) Tibial spur as in Figure 48.

(46) Lateral edge of metasomal tergum II very weakly sinuate, nearly straight.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area moderately granulate; (52) punctures separated by their width or less laterally, becoming impunctate centrally. (53) Clypeus granulate basally, apical two-thirds polished; (54) punctures separated by less than their width basally, less dense apically. (56) Meoscutum moderately shiny; (57) punctation as in Figure 548, punctures moderately coarse, dense and contiguous throughout, surface scabrous along anterior edge. (58) Scutellum nearly uniformly punctate, punctures at most separated by their width. (63) Dorsal surface of propodeum (Figure 599) strongly reticulate; (64) surface smooth, not alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane pale yellowish brown.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax mostly white to yellowish white, hairs on mesoscutum and scutellum brown; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hairs concolorous, brown. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

SPECIMENS EXAMINED.—32.

MEXICO. SAN LUIS POTOSI: Ciudad del Maiz, 5 mi E, 22 Aug 1954, 4700 ft, Univ. Kansas Mex. Exped. (19; KU), 1 mi E, 23 Jul 1962, 3200 ft, Univ. Kansas Mex. Exped. (29, sincludes holotype; KU).

### 36. Lasioglossum pharum (Vachal)

FIGURES 49, 600-604

Halictus pharus Vachal, 1904:475 [female; compared to Lasioglossum circinatum].—Cockerell, 1905a:90 [key].

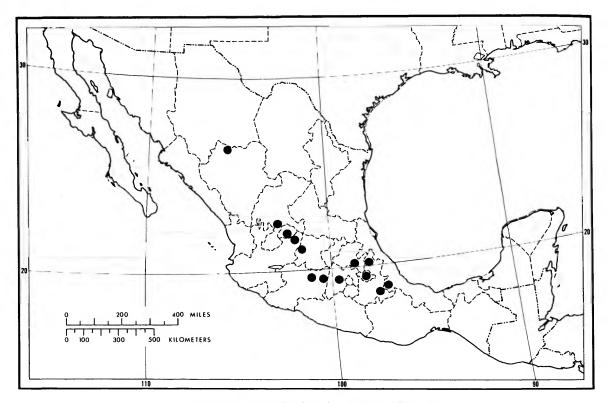

FIGURE 600.—Distribution of Lasioglossum pharum.

Lasinglossum pharum.—Moure and Hurd, 1986:63 [catalog].

TYPE MATERIAL.—The female holotype, in excellent condition, is in the Paris Museum (MNHNP) and is labeled

Museum Paris, Mexique, Sallé 1859/25, 59 [handwritten on circular label with green back]/Holotype [handwritten, red label]/pharus Vach.[al] \$ [handwritten]/Halictus pharus Vach[al] [handwritten].

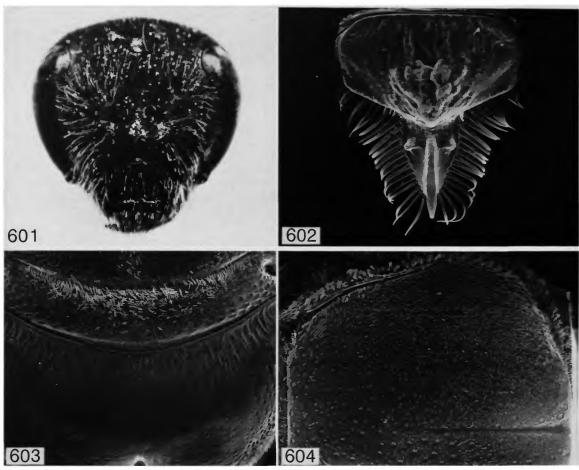

No paratypes were designated.

DISTRIBUTION (Figure 600).—Lasioglossum pharum is found at high elevations in central Mexico. Nearly all of the 52 known specimens are associated with elevation data that ranges from 5800–8800 feet.

DIAGNOSIS.—Lasioglossum pharum females can be recognized by their conspicuously doublypunctate mesoscutum (Figure 604), smooth dorsal propodeal surface (Figure 603), elongate head

(Figure 601, length/width ratio 0.90-0.97,  $\bar{x} =$ 0.93), and lack of a metasomal acarinarium. The similar L. circinatum has a mesoscutum that is only obscurely doubly-punctate, appearing completely granuloso-punctate under the light microscope (Figure 335) and a dull, granulate clypeal surface (polished, shiny in L. pharum). The only other New World Lasioglossum having the above diagnostic character combination is L. tropidonotum, which is readily distinguished by its median longitudinal mesoscutal keel (Figure 174) and the adpressed, short pubescence that entirely covers metasomal terga IV-V. Lasioglossum bajaense and L. uyacicola are superficially similar to L. pharum but both have metasomal acarinaria. The male of L. pharum is not known.

DESCRIPTION.—FEMALE: (1) Length 9.2–10.3 mm ( $\bar{x} = 9.7$ , n = 9); (2) wing length 2.6–3.1 mm ( $\bar{x} = 2.9$ , n = 9); (3) abdominal width 3.2–3.5 mm ( $\bar{x} = 3.3$ , n = 9).

FIGURES 601-604.—Lasioglossum pharum, female: 601, head; 602, labrum; 603, propodeum; 604, mesoscutum.

Structure: (4) Head elongate (Figure 601; length/width ratio 0.90-0.97,  $\bar{x}=0.93$ , n=9). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.80 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli slightly exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 602; (27) distal keel moderately narrow, nearly parallel-sided; (28) distal lateral-projections small, somewhat conical; (28) most fimbrial setae bluntly rounded apically.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, conspicuously interrupted by well-developed oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged near oblique sulcus, becoming rounded ventrally. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.67 the length of scutellum and about 1.3 times the length of metanotum, (41) not depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle not defined except for inconspicuous median V-shaped elevation without lateral rims; (44) lateral carinae

extending about two-thirds the length of posterior surface. (45) Tibial spur as in Figure 49.

(46) Lateral edge of metasomal tergum II very weakly sinuate, nearly straight.

Sculpture: (47) Face dull, granulate, (48) doubly-punctate, smaller punctures dense, separated by less than their width, larger punctures separated by 1-2 times their width. (51) Supraclypeal area obscurely granulate, moderately polished centrally; (52) punctures separated by their width or less laterally, becoming impunctate centrally. (53) Clypeus mostly polished, basal one-third very obscurely granulate; (54) punctures separated by less than their width basally, separated by their width on apical one-third. (56) Mesoscutum moderately dull; (57) punctation as in Figure 604, conspicuously doubly-punctate, smaller punctures separated by less than their width, becoming slightly less dense centrally, larger punctures separated by 3-5 times their width. (58) Scutellar punctation very sparse, obscurely doubly-punctate, smaller punctures separated by 2-3 times their width adjacent to median line, larger punctures scattered. (63) Dorsal surface of propodeum (Figure 603) nearly entirely smooth, weakly striolate laterally with very weak median striae confined to basal one-third; (64) surface extensively alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane hyaline.

Vestiture: (72) Unlike most species, hairs between vertex and antennae conspicuously simple, weakly recurved, contrasting with plumose hairs near antennae; (73) pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, hairs mostly white, dorsal hairs dark brown basally, becoming very light brown at midpoint of tibia. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

FLIGHT RECORDS.—Most L. pharum females

have been collected in August, but records range from late June through September and two more from December.

FLOWER RECORDS.—Ipomea 19; Ludwigia 19; Penstemon 19.

SPECIMENS EXAMINED.—519.

### 37. Lasioglossum rupticristum, new species

FIGURES 50, 485, 605

TYPE MATERIAL.—The female holotype of *L. rupticristum* is deposited in the Cornell University Collection. The specimen is in excellent condition and is labeled

ARIZ.[ona] Cochise Co. Chiricahua Mts. Onion Saddle, 7600' 12 Aug. 1972 G. & K. Eickwort/HOLOTYPE Lasioglossum rupticristum R.J. McGinley.

Twenty female paratypes listed in the "Specimens Examined" section are designated.

ETYMOLOGY.—The species epithet comes from the Latin *ruptura* (fracture, break) plus *crista* (ridge) and alludes to the broken pronotal

lateral carina, which differentiates this species from the very similar *L. heterorhinum* and *L. lampronotum*, which have a complete carina.

DISTRIBUTION (Figure 485).—Lasioglossum rupticristum is known from only 21 females that have been collected from Arizona, Colorado, and New Mexico.

DIAGNOSIS.—The short head (similar to Figure 458), granuloso-punctate anterior third of the mesoscutum (as in Figure 463), and absence of an acarinarium will distinguish L. rupticristum from all other New World Lasioglossum except L. heterorhinum. The pronotal lateral carina of the latter species is complete, whereas that of L. rupticristum is interrupted by an oblique lateral sulcus. Lasioglossum lampronotum is also similar to L. rupticristum but has a shiny mesoscutum with distinct anterior punctures and a complete pronotal lateral carina. Most specimens of L. rupticristum (including the holotype) are unusual in having yellowish orange pubescence (as opposed to white or yellowish brown) and faint metallic tints on the mesoscutum (not visible in all specimens). See L. heterorhinum "Diagnosis" for further details.

DESCRIPTION.—FEMALE: (1) Length 8.0–8.8 mm ( $\bar{x} = 8.3$ , n = 15); (2) wing length 2.3–2.5 mm ( $\bar{x} = 2.4$ , n = 15); (3) abdominal width 2.4–3.0 mm ( $\bar{x} = 2.8$ , n = 15).

Structure: (4) Head short (similar to Figure 458; length/width ratio 0.83-0.92,  $\bar{x}=0.87$ , n = 15). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.65 of its length below lower margin of eyes; (11) surface with obscure median longitudinal sulcation. (14) Distance between lateral ocellic subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 605; (27) distal keel broad in frontal view, spoon-shaped; (28) distal lateral projections somewhat weakly developed, rounded; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lat-

FIGURE 605.—Lasioglossum rupticristum, female labrum.

eral ridge narrowly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.81 the length of scutellum and about 1.2 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident medially as a very low V-shaped elevation with inconspicuous lateral rims, fading towards metanotum; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 50.

(46) Lateral edge of metasomal tergum 11 weakly sinuate.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) punctures separated by their width laterally, becoming sparse centrally, punctures separated by 3–4 times their width. (53) Clypeus mostly polished, obscurely granulate along basal edge; (54) punctation nearly uniform, punctures separated by their width or slightly less. (56) Mesoscutum shiny; (57) punctation as in Figure 463, punctures contiguous laterally, becoming granuloso-punctate anteriorly, less dense centrally, punctures separated by 1–2 times their width. (58) Scutellum sparsely

punctate adjacent to median line, punctures 2-3 times their width apart. (63) Dorsal surface of propodeum rugulose (similar to Figure 462); (64) surface obscurely alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration: (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hairs concolorous, very pale yellowish brown. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

FLIGHT RECORDS.—Lasing lossum rupticristum females have been collected from early May through October.

FLOWER RECORDS.—One female taken from *Cirsium*, and one from *Heliopsis* (both records from the Chiricahua Mountains, Cochise County, Arizona.

REMARKS.—Fourteen males from Arizona that may be conspecific with *L. rupticristum* females have been labeled

Lasioglossum sp. nr [near] desertum (male rupticristum ?) det. R.J. McGinley.

They are housed in the following collections: AMNH, CAS, CU, LACM, OrS, UAT. Their heads appear to be slightly longer than those of *L. desertum* and the hair fringe at the posterior edge of sternum V is much more conspicuous (similar to that of *L. argutum*, Figure 268). Because of the extreme uncertainty of this association these specimens are not formally treated here

SPECIMENS EXAMINED.—219.

UNITED STATES. ARIZONA: Cochise Co.: Chiricahua Mountains, 28 Sep 1960, 8000 ft, G.E. Bohart (12; USU); Portal, 9 mi W, 3 Jun 1959, L.A. # 38. Lasioglossum sandrae, new species

FIGURES 51, 395, 606

TYPE MATERIAL.—The holotype female is the property of the California Insect Survey, University of California, Berkeley, but is on loan deposit to the California Academy of Sciences, San Francisco. The specimen in excellent condition and is labeled

10.2 mi. W. Pueb.[la]-Ver.[acruz] boundary, Hwy [highway] 150, Pueb.[la] Mexico VII [Jul]-5, 1962/D.H. Janzen Collector/[green unlabeled paper point]/n.g. [new genus] det. G.C. Eickwort/HOLOTYPE Lasioglossum sandrae R.J. McGinley [red label].

The two female paratypes are in the collections of Cornell University and the University of California, Berkeley.

ETYMOLOGY.—This species is named in honor of Sandra Shanks (formerly of the Smithsonian Institution), who provided invaluable technical assistance and thoughtful discussion throughout the course of this project.

DISTRIBUTION (Figure 395).—Lasioglossum sandrae is known from only three females collected in the vicinity of Tehuacan in the Mexican state of Puebla.

DIAGNOSIS.—Females of *L. sandrae* can immediately be recognized by the short, adpressed, pale pubescence that entirely covers the mesoscutal disc. See the *L. eickworti* diagnosis for further details.

DESCRIPTION.—FEMALE: (1) Length 9.8–11.1 mm ( $\bar{x} = 10.4$ , n = 3); (2) wing length 3.0–3.2 mm ( $\bar{x} = 3.1$ , n = 3); (3) abdominal width 3.2–3.4 mm ( $\bar{x} = 3.3$ , n = 3).

Structure: (4) Head moderately short (similar

to Figure 396; length/width ratio 0.90-0.98, x = 0.93, n = 3). (7) Supraclypeal area evenly rounded ventrally, somewhat narrowly rounded dorsally near well-developed frontal carina. (8) area protuberant. (9) Clypeus projecting approximately 0.75 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation, broadly rounded dorsally but, unlike other species, with distinct semicircular depressed area along ventral edge. (14) Distance between lateral ocelli exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. Labrum as in Figure 606; (27) distal keel broad in frontal view, somewhat spoon-shaped: (28) distal lateral projections well developed, triangular; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle forming sharply pointed right angle; (33) pronotal lateral ridge incomplete, very narrowly interrupted by oblique lateral sulcus; (34) upper portion of lateral ridge strongly carinate, lower portion narrowly rounded. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.68 the length of scutellum and about 1.3 times

FIGURE 606.—Lasioglossum sandrae, female labrum.

the length of metanotum, (41) not depressed centrally, (42) posterior margin rounded; (43) propodeal triangle moderately well defined by low median V-shaped elevation and sharp-edged lateral rims, fading towards metanotum; (44) lateral carinae extending approximately two-thirds the length of posterior surface. (45) Tibial spur as in Figure 51.

(46) Lateral edge of metasomal tergum II broadly convex anteriorly, straight posteriorly (similar to that of *L. eickworti*).

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae. punctures contiguous. (51) Supraclypeal area extremely granulate; (52) punctures separated by 1-2 times their width laterally, becoming impunctate centrally. (53) Clypeus mostly polished, granulate along basal edge; (54) punctures obscure, separated by 2-3 times their width. (56) Mesoscutum moderately shiny; (57) punctures fine, extremely dense and contiguous throughout. (58) Scutellum uniformly punctate, punctures fine, nearly contiguous. (63) Dorsal surface of propodeum striolate laterally, basal half of median area ruguloso-striolate, posterior half smooth with obscure striae; (64) surface alveolated. (65) Metasomal tergum 1 moderately dull; (66) punctation fine, extremely dense, punctures nearly contiguous over most of dorsal surface, posterior rim granuloso-punctate.

Coloration: (71) Posterior two-thirds of wing membrane mostly hyaline, anterior one-third infuscated.

Vestiture: (74) Pubescence of head mostly pale yellowish brown, brown near antennae; unlike other species, hairs on vertex and gena very short, dense, somewhat adpressed. (75) Pubescence of thorax pale yellowish brown to dark brown; (76) unlike other species, mesoscutal and scutellar hairs very short, dense, adpressed, obscuring surface. (77) Hind tibial hairs virtually concolorous, dark brown with small apical patch of white hairs on dorsal surface. (78) Anterior hairs of metasomal tergum I yellowish brown, (79) basal hair bands of terga 11–IV yellowish white to pale yellowish brown. (80) Acarinarium

absent, anterior surface of tergum I with short, adpressed hairs (less conspicuous than those of *L. eickworti*) surrounded laterally by elongate hairs. (81) Unlike most species, basal hair bands of terga II–III weakly defined with short, adpressed hairs covering most of tergal surface; terga IV–V entirely covered by adpressed hairs.

FLIGHT RECORDS.—One female was collected in late June, the other two were taken in early July.

REMARKS.—L. sandrae, L. eickworti, and L. katyae probably comprise a natural group that possibly deserves subgeneric ranking. See "Remarks" section for L. eickworti.

SPECIMENS EXAMINED.—39.

MEXICO. PUEBLA: Puebla-Veracruz boundary, 10.2 mi W (Highway 150), 5 Jul 1962, D.H. Janzen (29, includes holotype; CAS, UCB): Tehuacan, 23 Jun 1951, H.E. Evans (19; CU).

### 39. Lasioglossum sisymbrii (Cockerell)

FIGURES 52, 132, 607-618

Halictus sisymbrii Cockerell, 1895:63 [female]; 1897:168 [male]; 1898a:46 [key]; 1898c:50 [key].—Crawford, 1906:297, 299, 300 [key, locality records].—Cockerell, 1906:294 [locality records]; 1907:241 [key]; 1908:119 [locality, floral records]; 1941:344 [locality and floral records, taxonomic notes].

Halictus sisimbrii.—Cockerell, 1897:165 [lapsus calami]. Halictus olympyiae var. subangustus Cockerell, 1898b:51. [New synonymy.]

Halictus olympiae var. subangustatus.—Crawford, 1906:301 [error for subangustus].

Lasioglossum olympiae var. subangustus.—Michener, 1951: 1107 [Nearctic catalog; emendation].—Hurd, 1979:1957 [Nearctic catalog].

Lasioglossum sisymbrii.—Michener, 1951:1107 [Nearctic catalog].—Linsley, 1962:159 [sleeping behavior.]—Linsley et al., 1963:18 [floral, locality records].—Moldenke and Neff, 1974:55 [locality and flower records].—Alcock and Gamboa, 1975:163 [predator].—Hurd and Linsley, 1975:28, tables 2, 9, 11, 13 [floral records].—Kumar et al., 1976:48 [locality record].—Stockhouse and Wells, 1978:127 [floral records].—Hurd, 1979:1958 [Nearctic catalog].—Hurd et al., 1980:27, 66.—Evans, 1982:573 [predator, Philanthus barbatus Smith].

TYPE MATERIAL.—The female lectotype, herein designated, is labeled

Ckll [Cockerell] 2752 on Sisymbrium [handwritten by Cockerell]/Type No. 3390 U.S.N.M. [red label]/H.[alictus] sisymbrii n. sp. [handwritten by Cockerell]/LECTOTYPE Halictus sisymbrii Cockerell des.[ignated by] McGinley [red label].

Cockerell's only reference to the type series in the original description is

Hab.[itat] College Farm, Las Cruces, N.M., April 16 1895; one swept from Sisymbrium canescens (Ckll. 2572).

The difference in Cockerell's numbers (2752 and 2572) is here taken to be the result of a typographical error. The one known paralectotype is labeled

Las Cruces NM [New Mexico]/Ckll. [Cockerell] 2878 on Melilotus [handwritten by Cockerell]/CoType No. 3390 U.S.N.M. [red label]/H.[alictus] sisymbrii [handwritten by Cockerell]/PARALECTOTYPE Halictus sisymbrii Cockerell des.[ignated by] McGinley [yellow label].

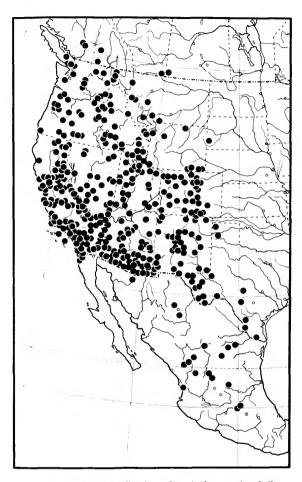

The lectotype has the basal hair band of metasomal tergum I nearly worn off and the paralectotype is missing the middle right leg, otherwise both are in excellent condition. They are in the National Museum of Natural History, Smithsonian Institution.

The female holotype of *Halictus olympyiae* var. subangustus is in the National Museum of Natural History, Smithsonian Institution, and is labeled

Olympia, Wash.[ington]/9 Type No. 12037 U.S.N.M. [red label]/H.[alictus] olympiae v.[ariety] subangustus Ckll. [Cockerell] TYPE. [handwritten by Cockerell].

The specimen is missing the last nine flagellomeres of the left antenna, and the basal hair band of metasomal tergum I is very worn, with only the lateral edges remaining. The worn hair band undoubtedly was the reason why Cockerell misidentified this specimen and thought it related to Lasioglossum olympiae. The original description of H. subangustus unfortunately included the typographical error of olympyiae for olympiae.

DISTRIBUTION (Figure 607).—Lasioglossum sisymbrii is the most common and most widespread Lasioglossum species west of the I00th meridian. It is found from southern Canada south to central Mexico (20° north latitude) and has been

NUMBER 429

FIGURE 607.—Distribution of Lasioglossum sisymbrii.

collected in all western, southwestern, and Rocky Mountain states. Two females were collected as far east as Baton Rouge, Louisiana sometime in the late 1800s (specimens labeled "Through C.V. Riley" in the National Museum of Natural History, Smithsonian Institution). Recent easternmost records are from central and southern Texas.

DIAGNOSIS.—The presence of a complete basal hair band on metasomal tergum I (Figure 132) will distinguish both sexes of Lasioglossum sisymbrii from all other New World Lasioglossum species. Lasioglossum pavonotum has widely interrupted, inconspicuous basal hair patches on ter-

gum I but is a highly distinctive metallic greenish blue bee, which cannot be confused with *L. sisymbrii*. The unique pale, translucent tegulae will identify the few *L. sisymbrii* specimens in which the basal hair band on tergum I has been worn or matted.

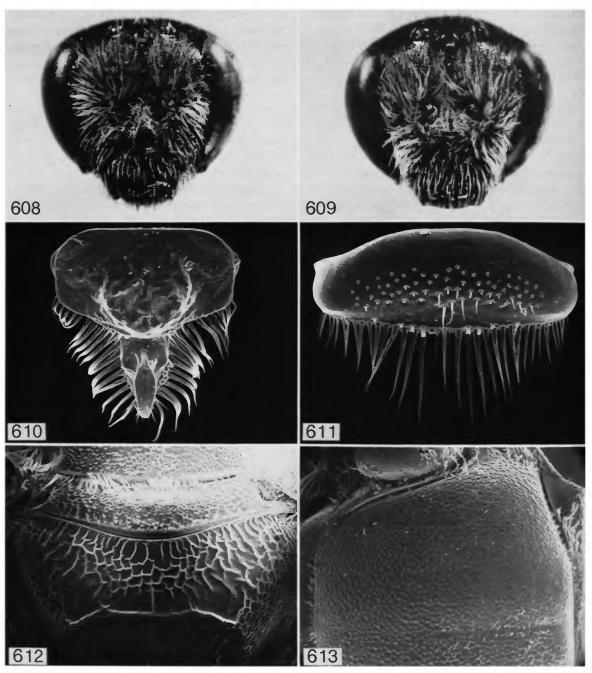

DESCRIPTION.—FEMALE: (1) Length 7.9–9.4 mm ( $\bar{x} = 8.5$ , n = 15); (2) wing length 2.2–2.5 mm ( $\bar{x} = 2.3$ , n = 15); (3) abdominal width 2.5–3.2 mm ( $\bar{x} = 2.8$ , n = 15).

Structure: (4) Head moderately short (Figure 608; length/width ratio 0.79-0.96,  $\bar{x}=0.86$ , n = 15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.75 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocellis slightly exceeding distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 610; (27) distal keel broad in frontal view, slightly spoon-shaped; (28) distal lateral projections very weakly developed, broadly rounded; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip rounded, not bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.75 the length of scutellum and about 1.4 times the length of metanotum, (41) not depressed centrally, (42) posterior margin nearly truncate (bowing slightly posteriad); (43) propodeal triangle weakly defined laterally; (44) lateral carinae completely encircling posterior surface. (45) Tibial spur as in Figure 52.

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area moderately granulate; (52) punctures separated by their width laterally, becoming only slightly less dense centrally. (53)

FIGURES 608-613.—Lasioglossum sisymbrii: 608, female head; 609 male head; 610, female labrum; 611, male labrum; 612, female propodeum; 613, female mesoscutum.

Clypeus obscurely granulate basally and medially to apex, highly polished apicolaterally; (54) punctures separated by less than their width basally and medially, apicolateral areas impunctate. (56) Mesoscutum shiny; (57) punctation as in Figure 613, punctation nearly uniform, dense, punctures separated by their width or less, slightly less dense centrally. (58) Scutellum nearly uniformly punctate, punctures slightly less dense adjacent to median line, separated by 1-2 times their width. (63) Dorsal surface of propodeum (Figure 612) strongly and completely striate with obscure transverse rugae to strongly reticulate; (64) surface smooth, not alveolated. (65) Metasomal tergum 1 shiny; (66) punctation fine, moderately dense, punctures separated by their width or slightly less.

Coloration: (70) Unlike other species, tegulae pale yellowish to translucent. (71) Wing membrane hyaline.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax mostly white, yellowish white along edges of mesoscutum and on scutellum and metanotum; (76) mesoscutal hairs moderately dense, conspicuously plumose; as in L. timberlakei, mesoscutal hairs along lateroposterior edge short, adpressed (adpressed hairs also along anterior edge). (77) Hind tibial hairs nearly concolorous, most hairs white, narrow band of dorsal hairs very light brown. (78) Anterior hairs of metasomal tergum 1 and (79) basal hair bands of terga I1-1V white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum 1. (81) Unlike other species, tergum I with complete basal hair band, narrowed medially.

MALE: Similar to female except as follows: (1) length 6.9–9.1 mm ( $\bar{x}=7.5$ , n=15); (2) wing length 1.9–2.4 mm ( $\bar{x}=2.1$ , n=15); (3) abdominal width 2.0–2.5 mm ( $\bar{x}=2.2$ , n=15). (4) Head as in Figure 609 (length/width ratio 0.81–0.91,  $\bar{x}=0.86$ , n=15). (5) Gena subequal to eye in width, (6) rounded, not produced posteriorly. (10) Clypeal surface rounded, not depressed or flattened. (23) Unlike other species, length of flagellomere 1 less than half the length

of flagellomere 2 (ratio 1:2 approximately 0.45). Labrum as in Figure 611; (24) distal process virtually absent; (25) basal area rounded medially, not depressed; (26) basal lateral depressions absent. (30) Mandible very short, not reaching opposing clypeal angle. (53) Clypeus weakly granulate, shiny; (54) punctation nearly uniform throughout, punctures separated by 1–2 times their width. (68) Clypeal maculation absent. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: (82) Hairs on sternum 1V short, suberect, without noticeable pattern; (83) posterior edge of sternum V with well-developed hair fringe, hairs becoming longer laterally, forming elongate lateral hair tufts similar to those of L. pacificum (Figure 561; hair fringe margin not so rounded as that of L. pacificum).

Terminalia: Sterna VII-VIII as in Figure 617; (85) median process of sternum VIII virtually absent, extremely short, rounded. Genitalia as in Figures 614-616; (86) gonobase moderately elongate; (87) gonostylus short, robust, narrowly rounded apically; (89) retrorse membranous lobe slightly reduced, very slender basally, gradually broadening to rounded apex; (90) volsella with moderately protruding flange but lacking prominent rounded lobe.

FLIGHT RECORDS (Figure 618).—Females of L. sisymbrii have been collected in every month from January through November (the January, October, and November records are all from Arizona and California). In the southwestern region females have been commonly collected in late March-early April and then again in late June-early July. Females in the northwestern region have been commonly collected only in June. Males have been collected from late March through November, with a definite peak in early July.

FLOWER RECORDS.—Label data strongly suggest that Lasioglossum sisymbrii is broadly polylectic. Hurd, LaBerge, and Linsley (1980) reported this species as being a "casual polylege" of Helianthus. Females have been collected from the flowers of Compositae, Cruciferae, and Leguminosae

FIGURES 614-617.—Lasioglossum sisymbrii, male: 614, genitalia, ventral view; 615, same, dorsal view; 616, volsella; 617, sterna VII-VIII.

in nearly equal proportions. Females with pollen loads have been taken from the flowers of 25 families. This is not meant to imply that all 25 families were actual pollen sources; however, this high number of families is suggestive of polylecty.

Summary: Females (953): Compositae 17%; Cruciferae 16%; Leguminosae 15%; Salicaceae 9%. Males (212): Compositae 43%; Leguminosae 23%. Total: 1165 in 49 families, 151 genera as follows:

Achillea 19, 36; \*Actinea 3(2)9, 26; Adenostemma 29; Agave 16; \*Agoseris 2(2)9; Allium 19; \*Amorpha 19(19)9, 16; Am-

# 40. Lasioglossum timberlakei, new species

FIGURES 53, 554, 619-630

TYPE MATERIAL.—The female holotype of *L. timberlakei* is in the National Museum of Natural History, Smithsonian Institution. The specimen is in good condition and is labeled

Los Angeles Co.[unty], CAL.[ifornia]/HOLOTYPE Lasio-glossum timberlakei R.J. McGinley [red label].

The holotype is what herein is referred to as the "dark form" of *L. timberlakei* (it has fulvous pubescence and linear, regularly spaced propodeal striae; see "Diagnosis" and "Remarks" sections). Two hundred sixty-three paratypes are designated and listed in the "Specimens Examined" section.

ETYMOLOGY.—As discussed in the "Remarks" section below, P.H. Timberlake's manuscript name "fulvohirtus," which refers to the fulvous hairs found among the dark forms in Riverside, California, is not an appropriate epithet, because many specimens (especially those found in the Sierra Nevada) have white pubescence. I therefore name this species after Mr. Timberlake, who first recognized this as a new species and who contributed so much to our knowledge of North American bees.

DISTRIBUTION (Figure 554).—Lasioglossum timberlakei is sympatric with the very similar L. pacificum along the Pacific coastal area of California and probably in Oregon as well. The dark form of L. timberlakei is primarily found in southern California (Los Angeles, Orange, Riverside, and Ventura counties), but one specimen has been taken in central California (Monterey County). The light form is found in Monterey County, south to San Diego County and north through the Sierra Nevada to southern Oregon.

DIAGNOSIS.—The obscure, poorly developed mesoscutal punctation (Figure 622), short, dense pubescence along the posterolateral mesoscutal edge, and highly sculptured dorsal propodeal surface (Figures 623, 624) will distinguish the females of *L. timberlakei* from other New World *Lasioglossum*. There are two forms of this species: a "dark form" with conspicuously fulvous pubescence and a linearly striated dorsal propodeal surface (Figure 623) and a "light form" with white pubescence and an irregularly striated propodeum (Figure 624). See "Remarks" section for further details.

Lasioglossum pacificum is very similar to L. timberlakei but is a larger bee (length 8.4-10.8 mm,  $\bar{x}=9.6$  mm vs. 7.4-10.2 mm,  $\bar{x}=8.7$  mm), has distinctly formed mesoscutal punctation (Figure 560), and elongate hairs along the posterolateral mesoscutal edge.

The males of *L. timberlakei* are similar to *L. pacificum* in having elongate hair tufts on the lateral edges of sternum V. However, the hair margin along the posterior edge of sternum V is more narrowly rounded in *L. timberlakei* (Figure 562) than in *L. pacificum*, in which the posterior hair margin is broadly rounded (Figure 561). The males of the light form of *L. timberlakei* are easily separated by their irregularly striate to nearly scabrous dorsal propodeal surface. See the "Diagnosis" of *L. pacificum* for further details concerning superfically similar species.

DESCRIPTION.—FEMALE: (I) Length 7.4–10.2 mm ( $\bar{x} = 8.7$ , n = 30); (2) wing length 2.2–2.8 mm ( $\bar{x} = 2.6$ , n = 30); (3) abdominal width 2.6–3.4 mm ( $\bar{x} = 2.9$ , n = 30).

Structure: (4) Head short (Figure 619; length/width ratio 0.79-0.92,  $\bar{x}=0.82$ , n=30). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.68-0.78 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal in length to 2 along dorsal surface. Labrum as in Figure 620; (27) distal keel narrow in frontal view,

nearly parallel-sided; (28) distal lateral projections virtually absent, evident as obscure swellings; (29) fimbrial setae acutely pointed.

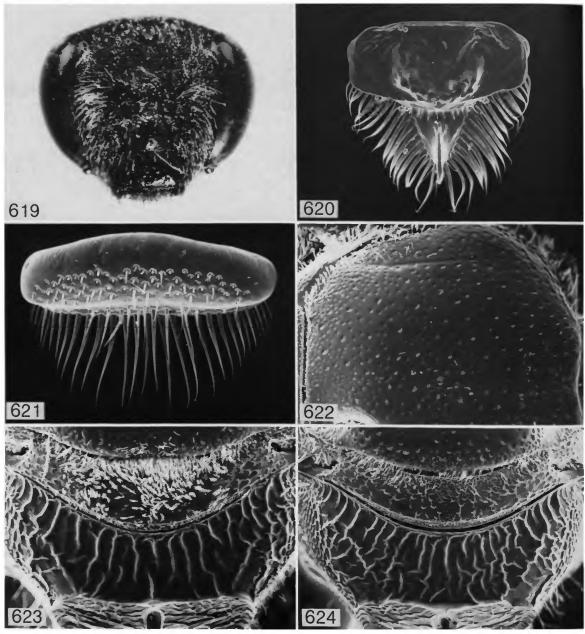

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.72–0.73 the length of scutellum and about 1.2–1.3 times the length of metanotum, (41) not depressed centrally, (42) posterior margin truncated (slightly bowed posteriad); (43) propodeal triangle weakly defined laterally; (44) lateral carinae completely encircling posterior surface. (45) Tibial spur as in Figure 53.

(46) Lateral edge of metasomal tergum II weakly sinuate.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) punctures separated by their width or less laterally, becoming only slightly less dense centrally. (53) Clypeus granulate basally, apical three-fourths polished; (54) punctures separated by less than their width basally, becoming less dense apically. (56) Mesoscutum shiny; (57) punctation as in Figure 622, indistinctly doubly-punctate, smaller punctures inconspicuous, 2-3 times their width apart, larger punctures poorly defined, widely spaced, 5-6 times their width apart. (58) Scutellum virtually impunctate adjacent to median line. (63) Dorsal surface of propodeum (Figures 623, 624) irregularly porcate, striae reaching posterior margin; (64) surface smooth, not alveolated. (65) Metasomal tergum I shiny; (66) punctation extremely fine, sparse posteriorly, punctures 2-3 times their width apart, punctures scattered anteriorly with large impunctate areas.

Coloration: (71) Wing membrane nearly hyaline, very lightly pigmented.

Vestiture: (74) Pubescence of head white to fulvous. (75) Pubescence of thorax white to fulvous; (76) mesoscutal hairs moderately sparse

FIGURES 619-624.—Lasioglossum timberlakei: 619, female head; 620, female labrum; 621, male labrum; 622, female mesoscutum; 623, female propodeum, dark form; 624, female propodeum, light form.

and plumose; as in *L. sisymbrii*, mesoscutal hairs along lateroposterior edge short, adpressed. (77) Hind tibial hairs concolorous, golden, to weakly differentiated in color with light brown dorsal hairs. (78) Anterior hairs of metasomal tergum I and (79) basal hair bands of terga II–IV yellowish white to pale yellowish brown. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I. (81) Unlike most species, basal hair band of tergum II conspicuously narrowed (not interrupted as in *L. pacificum*).

MALE: Similar to female except as follows: (I) length 6.4-8.0 mm ( $\tilde{x} = 7.3$ , n = 24); (2) wing length 2.0-2.3 mm ( $\bar{x} = 2.2, n = 24$ ); (3) abdominal width 1.8-2.2 mm ( $\bar{x} = 2.0, n = 24$ ). (4) Head short (length/width ratio 0.77-0.90,  $\bar{x} =$ 0.85, n = 24). (5) Gena narrower than eye, (5) rounded, not produced posteriorly. (10) Clypeal surface broadly rounded, not flattened or depressed. Labrum as in Figure 621; (24) distal process absent; (25) basal area rounded medially, not depressed; (26) basal lateral depressions absent. (30) Mandible very short, not reaching opposing clypeal angle. (53) Clypeus weakly granulate, shiny; (54) punctation nearly uniform throughout, punctures separated by 1-2 times their width. (68) Clypeal maculation absent. (69) Flagellum only very slightly paler ventrally than on dorsum. (72) Tarsi dark, concolorous with tibiae.

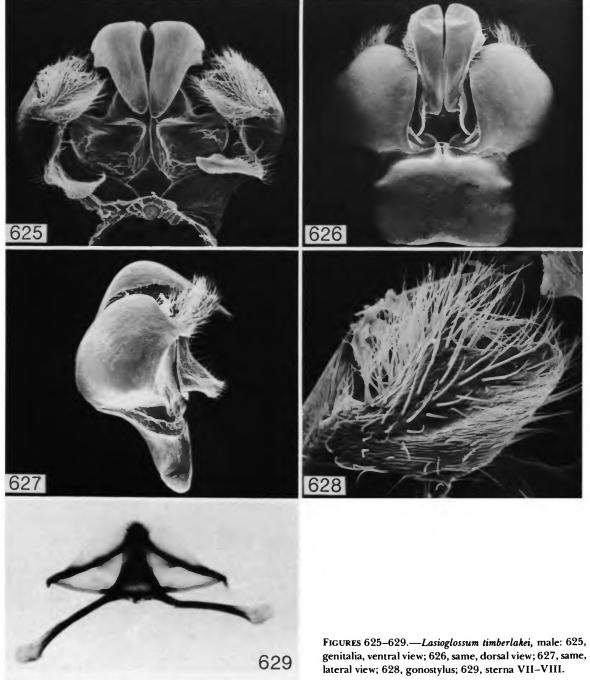

Vestiture: Sternal vestiture as in Figure 562; (82) sternum IV with apical fringe of suberect, plumose hairs; (83) sternum V with apical fringe of adpressed hairs that become longer laterally, forming lateral hair tufts similar to but not so developed as those of L. pacificum (margin of hair fringe sinuate, not evenly and broadly rounded as in L. pacificum).

Terminalia: Sterna VII-VIII as in Figure 629; (85) median process of sternum VIII absent except for very slight median convexity. Genitalia as in Figures 625-628; (86) gonobase moderately elongate; (87) gonostylus moderately large, robust and bluntly rounded, with conspicuous lateral fold; (89) retrorse membranous lobe slightly reduced, very slender basally, expanding

to rounded apex (similar to that of *L. sisymbrii*); (90) volsella broadly projecting laterally but lacking prominent lateral lobe.

REMARKS.—P.H. Timberlake apparently was the first worker to recognize L. timberlakei as being distinct from L. pacificum, to which it is very similar. Timberlake labeled a large series of specimens in the University of California, Riverside collection "Halictus fulvohirtus Timb." (an unpublished manuscript name; specimens from Riverside, California). These specimens, having fulvous pubescence and near linear, distinctly spaced propodeal striae (Figure 623), correspond to what I herein refer to as the dark form of L. timberlakei. While preparing the specimens for shipment to me, S.I. Frommer, Curator of the Riverside Entomology Collection, noted that Timberlake had associated with the specimens labeled "H. fulvohirtus" a shorter, unlabeled series. The latter specimens have white pubescence and irregularly striate dorsal propodeal surfaces (Figure 624; striae not linear and distinctly spaced as in other form). I herein refer to these specimens as the light form of L. timberlakei. Timberlake labeled a white form specimen in the University of California, Berkeley collection "Halictus n. sp." Whether or not these forms deserve individual specific status is uncertain at present. A few specimens appear to be somewhat intermediate in having conspicuously fulvous pubescence and an irregularly striate dorsal propodeal surface typical of the white forms. The dark form, known primarily from southern California, is most commonly collected in February and March. The light form is also found along the southern Pacific coastline but also occurs through the Sierra Nevada north to southern Oregon; it has most commonly been collected in June. The only early season records for the light form are one female collected in February and one female from March, both from Riverside County. Interestingly, both specimens are intermediate forms as described above.

Although hair coloration is noticeably variable, the propodeal sculpturing, though somewhat variable, appears to consistently differentiate

both forms at present, hence it is this feature that is used to separate the forms in this study, not hair coloration. However, given the variability of propodeal sculpturing in combination with the relative paucity of known specimens (especially males) and given the intermediate forms for hair color and propodeal sculpture, I hesitate recognizing two species at present. Some workers might designate two subspecies in this case but I prefer to avoid formalizing such uncertainty.

FLIGHT RECORDS (Figure 630).—Most of the L. timberlakei dark form specimens (84%) were collected by P.H. Timberlake in Riverside, California, from 1925 to 1958. Females were collected in every month from late January through early October except August. Most records (73%) are from February and March. The two males associated with the dark form were taken in October and December.

The light forms of *L. timberlakei* have most commonly been taken in June (56%), with the records ranging from February through September. The one light form taken in February was from Riverside, California; it appears to be an intermediate form in having rich, fulvous pubescence like the dark form but the irregularly striate propodeal surface of the light form. The one March record was also from Riverside County (Cedar Crest) and was an intermediate

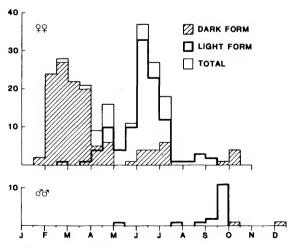

FIGURE 630.—Lasioglossum timberlakei flight records.

specimen like the above form. Other intermediate forms have been collected later in the year, for example: one female, Ventura County, California, 15 May 1971 (UCR); one female, Mono County, California, 25 August 1979 (CDA).

FLOWER RECORDS.—Dark form females (103): Salicaceae 40%; Cruciferae 35%; Compositae 7%. One male taken from *Baccharis*. Total: 104 in 10 familes, 16 genera as follows:

Alyssum 19; Amsinckia 19; Baccharis 59, 16; Brassica 19; Capsella 29; Cryptantha 19; \*Erodium 3(1)9; \*Eschscholtzia 1(1)9; Rhus 19; \*Salix 41(2)9; \*Sambucus 2(1)9; \*Schinus 2(1)9; \*Sedum 5(1)9; \*Sisymbrium 32(3)9; \*Solanum 3(2)9; Sonchus 29.

Light form females (16): Salicaceae 25%; Rhamnaceae 19%; Rosaceae 12%. Males (5): Compositae 100%. Total: 21 in 10 families, 15 genera as follows:

Arctostaphylos 1\,\text{?}, Aster 1\,\text{d}; \*Ceanothus 2(2)\,\text{\text{?}}; Chrysothamnus 2\,\text{d}; Cryptantha 1\,\text{\text{?}}; Eriogonum 1\,\text{\text{?}}; Gutierrezia 1\,\text{\text{d}}; Haplopappus 1\,\text{\text{d}}; \*Phacelia 1(1)\,\text{\text{?}}; Prunus 2\,\text{\text{?}}; Rhamnus 1\,\text{\text{?}}; \*Salix 4(2)\,\text{\text{?}}; Samucus 1\,\text{\text{?}}; \*Sisymbrium 1(1)\,\text{\text{?}}; Solidago 1\,\text{\text{?}}.

SPECIMENS EXAMINED.—Paratype dark forms: 127 (125°, 28°).

### 41. Lasioglossum titusi (Crawford)

FIGURES 54, 62, 631-644

Halictus Titusi Crawford, 1902:2 [female]; 1906:302 [locality records].

Lasioglossum titusi.—Michener, 1951:1107 [Nearctic catalog].—Linsley and MacSwain, 1959:22, 29 [flight records, association with Ranunculus, mites].—Linsley et al., 1963:42 [locality and flower records].—Whitsel and Schoeppner, 1971:223 [mites].—Moldenke and Neff, 1974:58 [locality and flower records].—Bohart and Youssef, 1976:193 [pollen preference].—Delfinado and Baker, 1976:286 [mites].—Eickwort, 1979:579 [mites].—Hurd, 1979:1958 [Nearctic catalog].—Hurd, et al., 1980:27, 66 [flower records].

TYPE MATERIAL.—The holotype of Halictus titusi could not be located and is presumed to be lost. In his original description, Crawford (1902) stated that "the specimens on which this paper is based are in the collection of the University of Nebraska, unless otherwise stated." Dr. Brett C. Ratcliffe kindly checked the Nebraska collection but could not locate any type material for this species. Although there are two specimens in the collection of the National Museum of Natural History labeled "cotype," they lack primary type status, because Crawford's only mention of the type series was "type from San Diego, Calif." Fortunately, Lasioglossum titusi is a very distinctive bee, and Crawford's original description

clearly associates the name with the "cotypes" and other specimens commonly believed to be conspecific. Designation of a neotype is unnecessary.

DISTRIBUTION (Figure 631).—Lasioglossum titusi has heretofore been reported only from California and Oregon (Hurd, 1979). It is now known to occur from southern British Columbia through Washington and south through coastal southern California to Baja California Norte, including East Anacapa, San Miguel, Santa Cruz, and Santa Rosa Islands. To the east the species follows the Rocky Mountain system into northern Utah and western Colorado.

DIAGNOSIS.—Females of Lasinglossum titusi can be readily recognized by their very sparse mesoscutal punctation (Figure 637). The mesoscutum is actually obscurely doubly-punctate

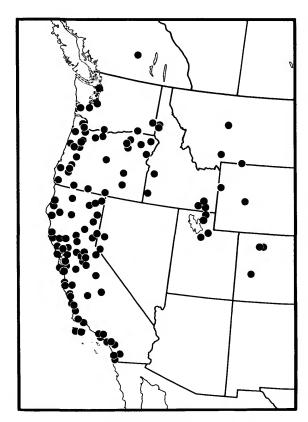

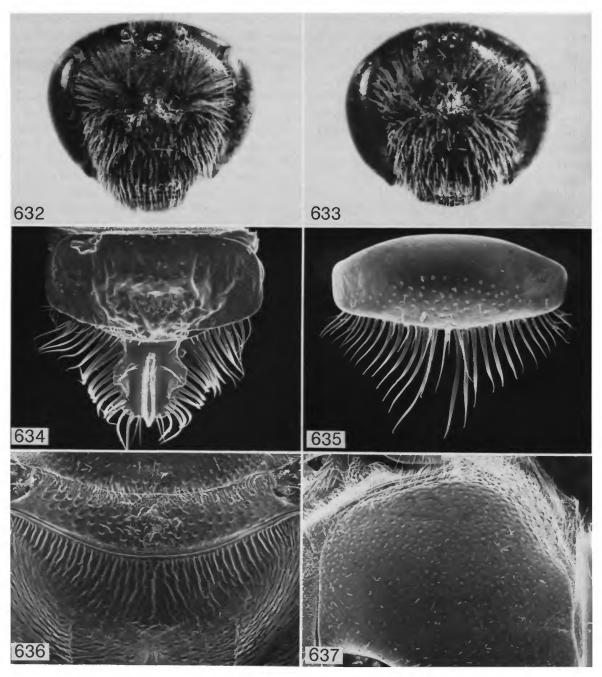

FIGURE 631.—Distribution of Lasinglossum titusi.

with the smaller, inconspicuous punctures separated by 2-4 times their width and the larger punctures separated by 2-3 times their width laterally, becoming extremely sparse centrally. The propodeal dorsal surface is regularly and distinctively striolate (Figure 636) and is unique among western Lasioglossum in being only slightly longer than the metanotum. Additional characters helpful in recognizing L. titusi are the moderately short head (Figure 632), the shiny and sparsely punctate vertex between the lateral ocellus and the compound eye (Figure 124), and the noticeably dull metasoma with relatively inconspicuous gray-white basal hair bands. Furthermore, this is the only Lasioglossum species associated with scutacarid mites that cling to the hairs on the posterior propodeal surface of the female bee (Figure 75; the histiostomatid mites associated with other Lasioglossum females are found on an acarinarium on the anterior surface of the first metasomal tergum of the host).

The mesoscutal punctation of male *L. titusi* is extremely sparse, more so than that of the female. The punctures are fine and inconspicuous on a highly polished mesoscutal surface. The fine mesoscutal punctation in combination with the yellow tarsi of all three pairs of legs will differentiate *L. titusi* males from all other North American *Lasioglossum* (other species with yellow tarsi have well-developed mesoscutal punctation). Also helpful in recognizing males of this species are the regularly striolate dorsal propodeal surface (similar to that of the female, Figure 636) and the relatively simple sternal vestiture (Figure 198).

DESCRIPTION.—FEMALE: Length 7.3-10.0 mm ( $\bar{x} = 8.8$ , n = 15); (2) wing length 2.3-2.7 mm ( $\bar{x} = 2.4$ , n = 15); (3) abdominal width 2.8-3.5 mm ( $\bar{x} = 3.2$ , n = 15).

Structure: (4) Head short (Figure 632; length/width ratio 0.85-0.92,  $\bar{x}=0.88$ , n=15). (7) Supraclypeal area evenly rounded, (8) very weakly protuberant. (9) Clypeus projecting approximately 0.75 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral

FIGURES 632-637.—Lasioglossum titusi: 632, female head; 633, male head; 634, female labrum; 635, male labrum; 636, female propodeum; 637, female mesoscutum.

ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 longer than 2 along dorsal surface. Labrum as in Figure 634; (27) distal keel narrow in frontal view, parallel-sided; (28) distal lateral projections well developed, unlike all other species, projections conspicuously truncated; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, broadly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip rounded, not bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum very short, about 0.54 the length of scutellum and subequal to metanotum in length, (41) not depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident medially as a low V-shaped elevation with weak lateral rims extending towards metanotum; (44) lateral carinae extending nearly to dorsal surface. (45) Tibial spur as in Figure 54.

(46) Unlike other species, lateral edge of metasomal tergum II broadly and evenly rounded (Figure 62).

Sculpture: (47) Face shiny, (48) densely punctate below ocelli (somewhat granular immediately below median ocellus), punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area extremely granulate; (52) uniformly but sparsely punctate, punctures separated by 3-4 times their width. (53) Clypeus granulate basally, obscurely granulate over apical two-thirds; (54) punctures minute basally, larger apically, uniformly separated by their width. (56) Mesoscutum dull; (57) punctation as in Figure 637, indistinctly doubly-punctate, smaller punctures very fine, inconspicuous, 2-4 times their width apart, larger punctures separated by 2-3 times their width laterally, becoming extremely sparse centrally. (58) Scutellum virtually impunctate adjacent to median line, punctures extremely fine and scattered. (63) Dorsal surface of propodeum (Figure 636) irregularly but distinctly striolate, striae reaching posterior margin; (64) surface very obscurely alveolated. (65) Metasomal tergum I dull, not noticeably granulate; (66) punctation very fine, obscure, moderately dense, punctures 1–2 times their width apart.

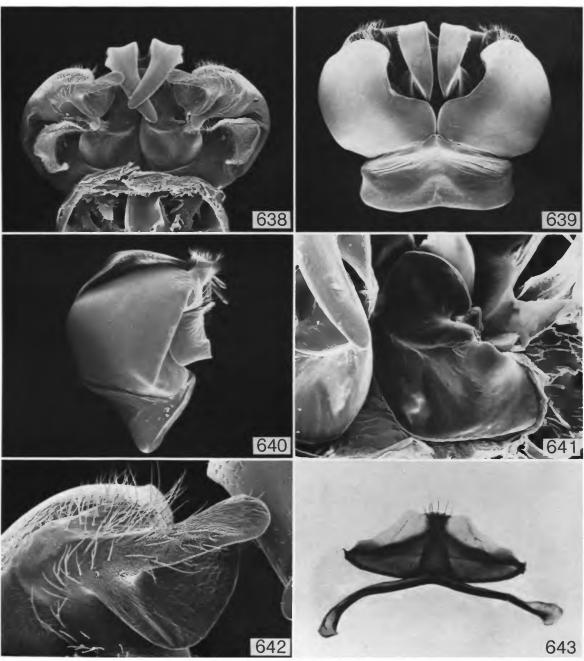

Coloration: (71) Wing membrane mostly hyaline, very obscurely infuscated towards apex.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax pale yellowish brown; (76) mesoscutal hairs somewhat dense, conspicuously plumose. (77) Hind tibial hairs concolorous, pale yellowish brown. (78) Anterior hairs of metasomal tergum I pale yellowish white, (79) basal hair bands of terga II—IV grayish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I (mites cling to propodeal hairs).

MALE: Similar to female except as follows: (1) length 7.1–8.5 mm ( $\bar{x} = 7.9$ , n = 15); (2) wing length 1.9–2.5 mm ( $\bar{x} = 2.3$ , n = 15); (3) abdominal width 2.0-2.9 mm ( $\bar{x} = 2.6$ , n = 15). (4) Head as in figure 633 (length/width ratio 0.79-0.91,  $\bar{x} = 0.85$ , n = 15). (5) Gena slightly wider than eye, (6) rounded, not produced posteriorly. (10) Clypeal surface broadly rounded, not flattened or depressed. (23) Unlike most species, flagellomere 1 relatively long compared to flagellomere 2 (ratio 1:2 approximately 0.87). Labrum as in Figure 635; (24) distal process absent; (25) basal area rounded medially, not depressed; (26) basal lateral depressions very weakly developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctation nearly uniform throughout, punctures separated by 1-2 times their width. (68) Clypeal maculation usually present, sometimes reduced or rarely absent. (69) Flagellum entirely dark or light brown ventrally and contrasting with dark dorsum. (72) Tarsi yellow, contrasting with dark tibiae.

Vestiture: Sternal vestiture as in Figure 198; (82) hairs on sternum IV moderately short, suberect, without noticeable pattern; (83) hairs on sternum V mostly short, inconspicuous except for small patch of erect hairs on lateral edge of sternum and characteristic fringe of short hairs along the posterior sternal edge.

Terminalia: Sterna VII-VIII as in Figure 643; (85) sternum VIII without median process. Genitalia as in Figures 638-642; (86) gonobase

FIGURES 638-643.—Lasioglossum titusi, male: 638, genitalia, ventral view; 639, same, dorsal view; 640, same, lateral view; 641, volsella; 642, gonostylus; 643, sterna VII-VIII.

moderately elongate; (87) gonostylus robust, broadly rounded to truncate apicially, surface conspicuously concave as viewed ventrally; (89) retrorse membranous lobe very slender basally, expanding to moderately broad distal portion (unlike other species, inner margin of lobe with row of conspicuously large, plumose setae); (90) volsella broadly rounded laterally, lacking prominent lobe.

FLIGHT RECORDS (Figure 644).—Female L. titusi have been collected in every month; however, 74% of the specimens examined were collected from May to July. Female records from the southwest region peak in late May, whereas those from the northwest peak in late June. The two specimens collected in November and January were from Riverside County, California; the one specimen collected in December was from Yolo County in the Central Valley of California. Male records are most common from July to September but range from May to early November, with one male collected on 11 January 1926, by P.H. Timberlake in Riverside, California.

FLOWER RECORDS.—Lasing lossum titusi is unusual among Lasing lossum species in showing some level of oligolectic behavior. This was first mentioned by Bohart and Youssef (1976), who stated that this species "collects pollen only from

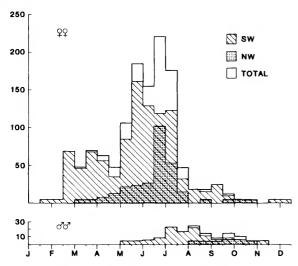

FIGURE 644.—Lasioglossum titusi flight records.

ligulate composites (unpublished)." Hurd, La-Berge, and Linsley (1980) reported this species as being a "casual polylege" of *Helianthus*. Of the 374 females examined in this study that had associated floral data, 312 (83%) were collected on composite flowers; 112 of these specimens were noted to have full or nearly full scopal pollen loads and 111 of them were taken on composites (one was taken from *Calochortus*). Although the relationship between floral label data and actual source of scopal pollen are tenuous without pollen analysis, the obvious trend in this case is highly supportive of Bohart and Youssef's claim for oligolecty.

Summary: Females (365): Compositae 83%; Ranunculaceae 3%. Males (29): Compositae 93%; Plantaginaceae 7%. Total: 394 in 17 families, 53 genera as follows:

\*Agoseris 78(5)\(\text{P}\); Anthemis 3\(\text{P}\); \*Aster 6(1)\(\text{P}\), 1\(\text{S}\); Astragalus 1\(\text{P}\); Baeria 8\(\text{P}\); Balsamorhiza 1\(\text{P}\); \*Blennosperma 6(2)\(\text{P}\); Blepharipappus 15\(\text{P}\); Brassica 5\(\text{P}\); \*Calochortus 1(1)\(\text{P}\); Calycadenia 1\(\text{S}\); Ceanothus 1\(\text{P}\); Chrysanthemum 1\(\text{P}\); Coreopsis 3\(\text{P}\); \*Cosmos 7(7)\(\text{P}\); \*Crepis 1(1)\(\text{P}\); Cryptantha 7\(\text{P}\); Encelia 4\(\text{P}\); Fritillaria 1\(\text{P}\); Godetia 1\(\text{P}\); Grindelia 6\(\text{P}\), 2\(\text{S}\); \*Helianthus 28(24)\(\text{P}\); \*Hemizonia 12(3)\(\text{P}\), 1\(\text{S}\); Heterotheca 1\(\text{P}\); Hypericum 1\(\text{P}\); \*Hypochaeris 56(37)\(\text{P}\); \*Lasthenia 9(4)\(\text{P}\); \*Layia 19(11)\(\text{P}\), 4\(\text{S}\); Limnanthes 1\(\text{P}\); Lomatium 1\(\text{P}\); \*Madia 7(5)\(\text{P}\), 1\(\text{S}\); Malacothrix 1\(\text{P}\); Melilotus 2\(\text{P}\); Mentha 1\(\text{P}\); Mesembryanthemum 1\(\text{P}\); Nemophila 2\(\text{P}\); Parthenium 21\(\text{P}\), 3\(\text{P}\); Picris 2\(\text{P}\), 1\(\text{P}\); Plantago 2\(\text{S}\); Ranunculus 15\(\text{P}\); Salix 1\(\text{P}\); Sisymbrium 1\(\text{P}\); \*Solidago 1(1)\(\text{P}\); Stenotopsis 1\(\text{P}\); Stephanomeria 1\(\text{P}\), 1\(\text{P}\); Taraxacum 13\(\text{P}\); Trifolium 1\(\text{P}\); Triteleia 1\(\text{P}\); \*Wyethia 2(1)\(\text{P}\).

MITE ASSOCIATES.—Unlike other species of New World Lasioglossum, L. titusi is associated with a scutacarid mite, Imparipes vulgaris Delfinado and Baker (Linsley and MacSwain, 1959; Delfinado and Baker, 1976; Eickwort, 1979). See introductory section on "Mite Associations" for further details.

Specimens Examined.—1473 (13159, 1588).

## 42. Lasioglossum transvorsum (Vachal)

FIGURES 55, 645-658

Halictus transvorsus Vachal, 1904:472 [female].—Cockerell, 1905a:90 [key].

Lasioglossum transvorsum.—Moure and Hurd, 1986:65 [catalog].

TYPE MATERIAL.—Vachal based his description of *Halictus transvorsus* on two females labeled "Angang. Mex." without designating a holotype. Moure and Hurd (1986) state that "one of two females in the type series was labeled by one of us (Moure) in March, 1958 as the lectoholotype and is now so designated." Neither one of the specimens now has this lectotype label but one has been recently labeled "HOLOTYPE." I assume this specimen is the one Moure intended to be the lectotype and I have reattached a lectotype label with the designation attributed to Moure. The full label data are

Angag.[ueo?]; MUSEUM PARIS Amerique COLL. O. SICHEL 1867/HOLOTYPE [handwritten on red label]/Hal.[ictus] & transvorsus Vach.[al] [handwritten by Vachal?]/Halictus transvorsus Vach. [al] [recently handwritten]/LECTOTYPE Halictus transvorsus Vachal des.[ignated by] Moure.

The lectotype and paralectotype are in the Paris Museum (MNHNP). The former specimen is in poor condition, having been repinned as evidenced by the very large hole in the mesoscutum (which is also cracked) and the two pin holes in the venter of the thorax. The last 9 flagellomeres of the left antenna are missing and the left forewing had been broken off and crudely reglued to the pleuron. During shipment in February 1984, the abdomen broke off; it is now contained in a small capsule attached to the insect pin.

The type-locality "Angang." refers to either Angangueo railway station [19°36′N, 100°-17′W] or Mineral de Angangueo [19°37′N, 100°18′W]. This locality is apparently in the state of Michoacan.

DISTRIBUTION (Figure 645).—The known distribution of *Lasioglossum transvorsum* is confined

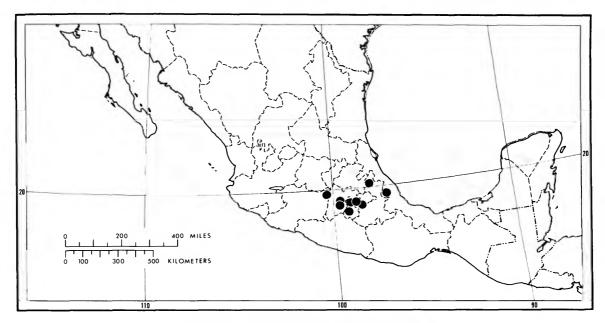

FIGURE 645.—Distribution of Lasinglossum transvorsum.

to a restricted area of southcentral Mexico near Mexico City. Only 38 females and 6 males have been collected.

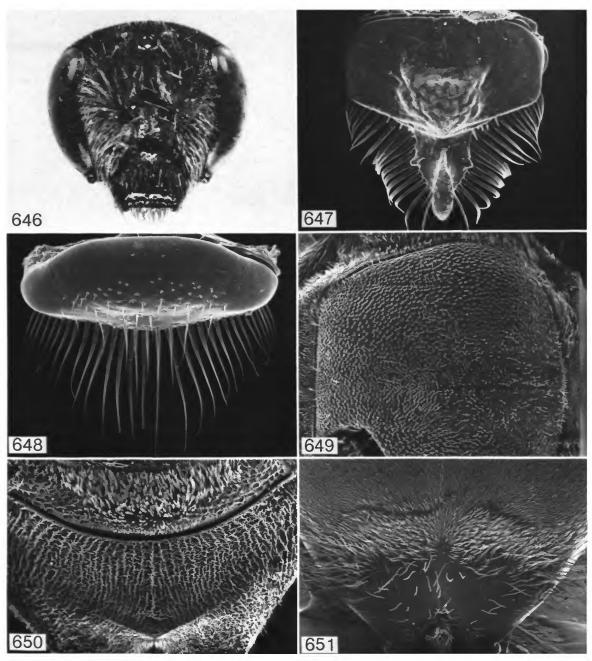

DIAGNOSIS.—Both sexes of L. transvorsum can be recognized by the non-elevated mesoscutal anterior edge (Figure 87; compare with the normally elevated mesoscutal edge in Figure 90). The only other Lasioglossum having a non-elevated mesoscutum is L. coriaceum from the eastern United States. Aside from the great difference in distributions, L. transvorsum differs from L. coriaceum in having a densely punctate mesoscutum (Figures 649, 359) and in lacking a metasomal acarinarium (Figures 651, 72).

The dorsal propodeal surface of both sexes is diagnostic in having a strongly elevated V-shaped posterior rim (Figure 650). Lasioglossum pallicorne also has an elevated propodeal rim; however, it is more strongly developed than that of L. transvorsum and encloses a relatively smooth propodeal surface (Figure 574; the propodeal surface of L. transvorsum is striolate throughout). Furthermore, these two species differ in that L.

transvorsum lacks an acarinarium, which is present in L. pallicorne. Also helpful in identifying L. transvorsum is the nearly complete pronotal lateral carina, which is only minutely notched (Figure 11). Females are unique in having a conspicuous patch of short adpressed hairs on the anterior surface of tergum I (Figure 651).

DESCRIPTION.—FEMALE: (1) Length 8.3–10.9 mm ( $\bar{x} = 9.6$ , n = 15); (2) wing length 2.6–3.0 mm ( $\bar{x} = 2.8$ , n = 15); (3) abdominal width 2.5–3.0 mm ( $\bar{x} = 2.8$ , n = 15).

Structure: (4) Head elongate (Figure 646; length/width ratio 0.92-1.0,  $\bar{x}=0.95$ , n=15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.80 of it length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocellislightly exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 647; (27) distal keel broad in frontal view, spoon-shaped; (28) distal lateral projections small

FIGURES 646-651.—Lasioglossum transvorsum: 646, female head; 647, female labrum; 648, male labrum; 649, female mesoscutum; 650, female propodeum; 651, base of female tergum I showing adpressed, short hair patch.

but distinct, somewhat conical; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge complete, conspicuously elevated, oblique lateral sulcus poorly defined, extremely broad; (34) lower portion of lateral ridge sharply edged near oblique sulcus, becoming narrowly rounded ventrally. (35) Mesoscutal lip rounded, not bilobed, (36) not elevated from pronotum. (40) Dorsal surface of propodeum about 0.83 the length of scutellum and about 1.4 times the length of metanotum, (41) distinctly depressed centrally, (42) posterior margin broadly rounded with conspicuous median V-shaped projection; (43) propodeal triangle well defined medially by V-shaped elevation with conspicuous lateral rims, fading towards metanotum; (44) lateral carinae extending beyond midpoint of posterior surface, obscurely reaching dorsal surface. (45) Tibial spur as in Figure 55.

(46) Lateral edge of metasomal tergum 11 weakly sinuate.

Sculpture: (47) Face shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area moderately granulate; (52) punctures separated by their width laterally, becoming only slightly less dense centrally. (53) Clypeus granulate basally, apical two-thirds moderately polished; (54) punctures obscure basally, separated by less than their width, separated by their width centrally, apical edge largely impunctate. (56) Mesoscutum shiny; (57) punctation as in Figure 649, punctures somewhat coarse, contiguous throughout. (58) Scutellar punctation moderately sparse adjacent to median line, punctures 1-2 times their width apart. (63) Dorsal surface of propodeum (Figure 650) very strongly ruguloso-striolate, median striae not quite reaching posterior margin; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, extremely dense, punctures nearly contiguous.

Coloration: (71) Wing membrane pale yellowish brown with infuscated spot near apex.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax mostly

pale yellowish brown, white on pronotal lateral angle, pronotal lobe, metanotum and propodeum; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, ventral and lateral hairs white, dorsal hairs brown to dark brown. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium absent, but tergum I with unique dense patch of short, fine, adpressed hairs on anterior edge (Figure 651).

MALE: Similar to female except as follows: (1) length 7.3–10.1 mm ( $\bar{x} = 8.8$ , n = 5); (2) wing length 2.3-2.7 mm ( $\bar{x} = 2.5$ , n = 6); (3) abdominal width 2.0-2.6 mm ( $\bar{x} = 2.3$ , n = 5). (4) Head elongate (length/width ratio 0.96-1.04,  $\bar{x} = 1.0$ , n = 6). (5) Gena slightly wider than eye, (6) moderately produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. (23) Unlike most species, flagellomere 1 relatively long compared to flagellomere 2 (ratio 1:2 approximately 0.91). Labrum as in Figure 648; (24) distal process virtually absent; (25) basal area very weakly depressed medially, nearly rounded; (26) basal lateral depressions absent. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate, shiny; (54) punctures well formed, nearly contiguous basally, larger and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 652; (82) hairs on sternum IV moderately elongate, suberect, posterior edge of sternum with noticeable fringe of pale hairs; (83) hairs on sternum V short, suberect, posterior sternal edge with broadly rounded, widely separated lateral hair lobes (similar to those of L. heterorhinum, Figure 464).

Terminalia: Sterna VII-VIII as in Figure 658; (85) sternum VIII with moderately broad, apically truncate, semicircular median process. Genitalia as in Figures 653–657; (86) gonobase elongate; (87) gonostylus moderately elongate, slender, narrowly rounded apically; (89) retrorse membranous lobe moderately broad (unlike

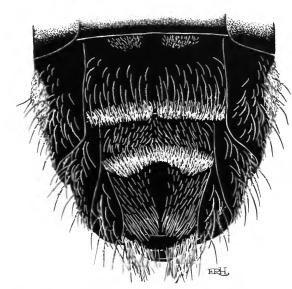

FIGURE 652.—Lasioglossum transvorsum, male sternal vestiture.

other species except *L. asaphes*, apex of gonocoxite near base of retrorse lobe with large, medially directed membranous lobe); (90) volsella lacking prominent lateral lobe.

FLIGHT RECORDS.—Because of the paucity of specimens, little can be said about the flight-activity patterns of *L. transvorsum*. Females have been collected in most months of the year, whereas males have been taken in January, April, July, and December.

FLOWER RECORDS.—Two females from the state of Mexico (Amecameca) were taken from *Heterotheca chrysopsidis*.

MITE ASSOCIATES.—Lasioglossum transvorsum females do not have an acarinarium, and none of the 38 females examined carried mites. However, one male from Morelos (Tres Cumbres, 3 mi S) had many hypopodes on the abdominal sterna, several on the hind femora, one each on the middle femora, one of the pronotum, and a few on the genae. Such a scattered positioning of hypopodes is not found in Lasioglossum males normally associated with mites. The positioning of mites on the abdominal sterna was not seen in any other male in this study.

## 43. Lasioglossum tricnicos (Vachal)

FIGURES 56, 659-667

Halictus tricnicos Vachal, 1904:474 [female].—Cockerell, 1905a:90 [key].

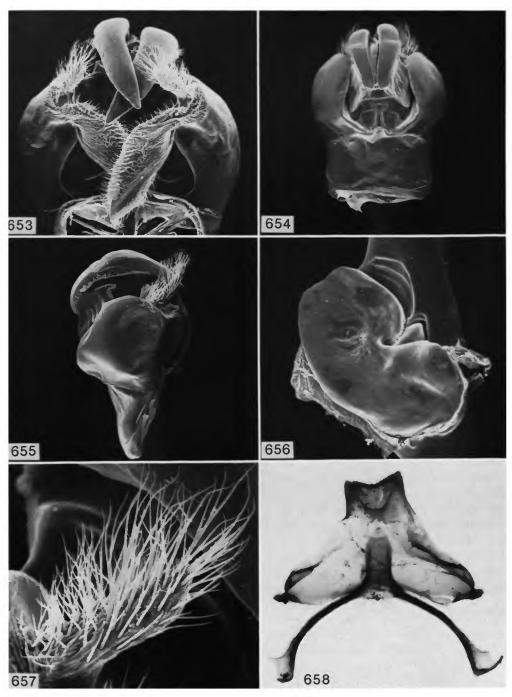

Lasioglossum tricnicos.—Moure and Hurd, 1986:66 [catalog].

TYPE MATERIAL.—The female holotype is labeled

Museum Paris Mexique coll. O. Sichel 1867/Sierra [illegible letter] Rivas [handwritten]/Mex[ico] [18]63 [illegible word, presumably the collector name] [handwritten]/Holotype [handwritten on red label]/tricnicos Vach[al] [handwritten]/Halictus tricnicos Vach.[al] [handwritten].

The specimen has an old pin-hole in the left pleuron but otherwise is in excellent condition. It is housed in the Paris Museum (MNHNP).

DISTRIBUTION (Figure 659).—Lasioglossum tricnicos is presently known from only five females and three males, which were collected in five south-central Mexican states: Distrito Federal, Mexico, Michoacan, Morelos and Tlaxcala.

FIGURES 653-658.—Lasioglossum transvorsum, male: 653, genitalia, ventral view; 654, same, dorsal view; 655, same, lateral view; 656, volsella; 657, gonostylus; 658, sterna VII-VIII.

FIGURE 659.—Distribution of Lasinglossum tricnicos.

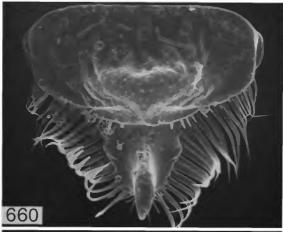

Two specimens were collected at elevations of 8500 and 9600 feet.

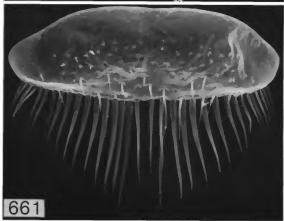

DIAGNOSIS.—Lasioglossum tricnicos can be recognized by the following character combination: posterior two-thirds of wing membrane hyaline, anterior third along costal margin heavily infuscated (as in Figure 177); mesoscutum very finely and completely granuloso-punctate (as in Figure 1); pronotal lateral angles densely covered with conspicuous white pubescence. The above characters will distinguish L. tricnicos from all other New World Lasioglossum except L. crocoturum, which is easily differentiated by having the metasomal terga IV-V nearly entirely covered by short, dense, adpressed hairs (Figure 1) and by having a relatively longer head than that of L. tricnicos. Other Lasioglossum having the anterior third of the wing membrane infuscated along the costal margin are L. eickworti, L. sandrae, and L. katyae, but these are conspicuously larger bees than L. trienicos (body length 9.5-11.9 mm versus 8.4-9.0 mm) and generally occur south of the known distribution of *L. tricnicos* (Figure 395; only L. sandrae is known to be potentially sympatric with *L. tricnicos* and can be recognized by the conspicuous mat of short hairs covering the mesoscutum).

The infuscated anterior edge of the forewing and the erect, lateral hair tufts on sternum V (Figure 662) will distinguish the males of *L. tricnicos* from those of all other known *Lasioglossum*.

DESCRIPTION.—FEMALE: (1) Length 8.4–9.0 mm ( $\bar{x} = 8.7$ , n = 3); (2) wing length 2.5–2.6 mm ( $\bar{x} = 2.5$ , n = 3); (3) abdominal width 2.5 mm ( $\bar{x} = 2.5$ , n = 3).

Structure: (4) Head short (similar to Figure 545; length/width ratio 0.87-0.89,  $\bar{x}=0.88$ , n = 3). (7) Supraclypeal area evenly rounded, (8) very weakly protuberant. (9) Clypeus projecting approximately 0.73 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (13) Distance between lateral ocelli slightly exceeded by distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 660; (27) distal keel moderately broad in frontal view, lateral edges bowed; (28) distal lateral projections weakly developed,

FIGURES 660, 661.—Lasioglossum tricnicos labra: 660, female; 661, male.

rounded; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle broadly obtuse; (33) pronotal lateral ridge incomplete, narrowly interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge moderately edged. (35) Mesoscutal lip very weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.75 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle very weakly defined laterally, evident medially by low, rounded V-shaped elevation without lateral rims; (44) lateral carinae

extending approximately two-thirds the length of posterior surface. (45) Tibial spur as in Figure 56.

(46) Lateral edge of metasomal tergum II very weakly sinuate.

Sculpture: (47) Face moderately shiny, (48) densely and uniformly punctate between ocelli and antennae, punctures contiguous. (51) Supraclypeal area extremely granulate; (52) uniformly and densely punctate, punctures separated by their width or less. (53) Clypeus granulate basally, apical two-thirds polished; (54) punctures separated by less than their width basally, less dense apically. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 1, punctures extremely dense, granuloso-punctate throughout. (58) Scutellum uniformly granuloso-punctate. (63) Dorsal surface of propodeum weakly ruguloso-striolate laterally, striae becoming very obscure medially, almost ruguloso-granulate; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) granuloso-puntate throughout.

Coloration: (71) Posterior two-thirds of wing membrane mostly hyaline, anterior one-third along costal margin deeply infuscated.

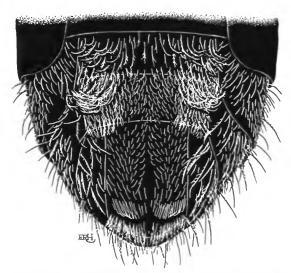

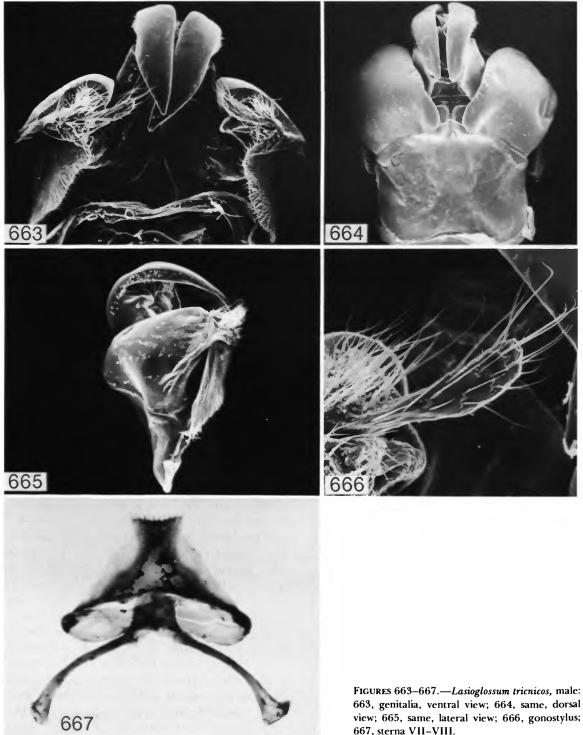

FIGURE 662.—Lasioglossum tricnicos, male sternal vestiture.

view; 665, same, lateral view; 666, gonostylus; 667, sterna VII-VIII.

Vestiture: (74) Pubescence of head white to very light brown near antennae, becoming brown on vertex. (75) Pubescence of thorax white on pronotal lateral angle, pronotal lobes, metanotum and propodeum; hairs on pronotal lateral angle thick, conspicuous; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, most hairs white, dorsal hairs brown to dark brown. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II–IV white to yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 7.8-8.1 mm ( $\bar{x} = 8.0$ , n = 3); (2) wing length 2.1–2.2 mm ( $\bar{x} = 2.1$ , n = 3); (3) abdominal width 1.8-2.0 mm ( $\bar{x} = 1.9$ , n = 3). (4) Head short (length/width ratio 0.90-1.0,  $\bar{x} = 0.95$ , n = 3). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (10) Clypeal surface broadly rounded, only faintly depressed along ventral edge. Labrum as in Figure 661; (24) distal process absent; (25) basal area depressed medially; (26) basal lateral depressions conspicuously developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate basally, apical two-thirds polished; (54) punctures well formed, nearly contiguous basally, apical two-thirds with scattered, moderately large punctures. (68) Clypeal maculation present. (69) Flagellum brown ventrally, slightly paler than dark dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 662; (82, 83) hairs on sterna IV and V short, suberect medially, becoming longer and erect laterally, forming noticeable elongate hair tufts.

Terminalia: Sterna VII-VIII as in Figure 667; (85) sternum VIII with moderately broad, apically truncate, semicircular median process. Genitalia as in Figures 663–666; (86) gonobase elongate; (87) gonostylus elongate, slender; (89) retrorse membranous lobe moderately broad; (90) volsella with prominent lateral lobes.

FLIGHT RECORDS.—One of the five known females of *L. tricnicos* was collected in June; the other female with flight data was collected in

October. The three males were collected in June, July, and December.

FLOWER RECORDS.—One female taken from Stylosanthes (Leguminosae) in the state of Tlax-cala.

Additional Specimens Examined.—7 (42,  $3\delta$ ).

#### THE trizonatum GROUP

SPECIES INCLUDED.—Lasioglossum anhypops, new species; L. egregium (Vachal); L. mellipes (Crawford); L. trizonatum (Cresson).

DISTRIBUTION (Figure 668).—The trizonatum group is very common throughout much of the western United States and southern Canada. The group ranges from Moresby Island off the coast of British Columbia, south to southern California, Arizona, and New Mexico. The species do not occur east of the 100th meridian, reaching central Colorado and the western edge of the Dakotas.

DIAGNOSIS.—Females of this group are rather nondescript and have commonly been confused with a variety of other Lasioglossum species. They are moderately large (body length  $\bar{x} = 8.2-9.7$ mm) with elongate heads (Figures 670, 683, 697, 709; length/width ratio 0.93-1.02). The posterior margin of the dorsal propodeal surface is rounded (Figure 113; not broadly rounded, Figure 110; or truncate, Figure 127, as in most other species). The dorsal propodeal surface is elongate and ruguloso-striolate. noticeably Lasioglossum colatum has a similar propodeal surface but has a shorter head (Figure 339, length/ width ratio 0.91) and distinctive short, adpressed hairs on the anterior surface of tergum I (Figure 351). The posterior margin of the dorsal propodeal surface is rounded and lacks the slightly

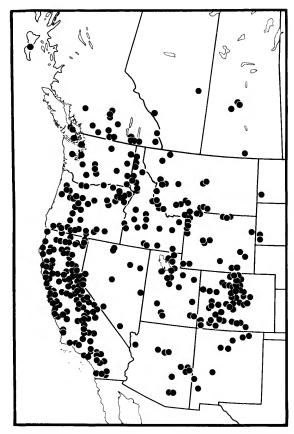

FIGURE 668.—Distribution of Lasioglossum trizonatum group.

elevated lateral rims that are found in females of the similar forbesii group (Figure 414). Most females of the trizonatum group have an acarinarium on the anterior surface of tergum I, the glabrous surface of which is relatively small and indistinctly delimited by relatively sparse, elongate fringe hairs (Figures 693, 711; the fringe hairs are dense and form a much more sharply defined border in the similar forbesii group, Figures 407–409, and L. morrilli, Figure 525). Females of L. anhypops lack an acarinarium (Figure 85) but can be recognized by the sharply excavated lateral edge of tergum II (Figures 154).

Among species occurring in the western United States, males of the *trizonatum* group can usually be recognized by their relatively flat cly-

peal surfaces and their conspicuously elongate heads, which appear longer than broad (Figures 684, 698, 710, length/width ratio  $\bar{x} = 0.95-1.02$ for four species). The shortest heads are those of L. anhypops (Figure 671, length/width ratio  $\bar{x} =$ 0.93, n = 15). Lasioglossum athabascense males have moderately elongate heads (Figure 289, length/width ratio  $\bar{x} = 0.95$ ) but have a broadly rounded clypeal surface and elongate, erect lateral hair tufts on sternum V (Figure 294; these tufts are similar to those of L. egregium where the head is obviously longer (Figure 684, length/ width ratio  $\bar{x} = 0.98$  and the clypeal surface flat). Other western species with moderately elongate headed males are L. pavonotum, which is metallic blue-green (Figure 585, length/width ratio  $\bar{x} =$ 0.90); L. zonulum, which has a unique vestiture pattern on sternum VI (Figure 744; length/width ratio  $\bar{\mathbf{x}} = 0.93$ ); L. colatum, which has an obviously rounded clypeal surface and shorter head (Figure 340, length/width ratio  $\bar{x} = 0.90$ ); and L. paraforbesii (Figure 435, length/width ratio  $\bar{x} = 0.93$ ), which has yellow hind tarsi and very short inconspicuous hairs on sternum V (L. mellipes hind tarsi yellowish orange and sternum V with erect, lateral hair tufts and/or a median rosette of erect hairs (Figures 701, 702). The males of L. channelense, long considered to be conspecific with L. trizonatum, have conspicuously elongate mandibles (Figure 320) and a virtually complete pronotal lateral carina (obviously incomplete in trizonatum males). The most similar male to those of the trizonatum group is that of L. morrilli. The latter species has a very elongate head (length/ width ratio  $\bar{x} = 0.95$ ) but can be distinguished by its virtually impunctate and rounded clypeal surface. Furthermore, the gonostylus of L. morrilli is truncate apically (Figure 233), which differs from the narrowly rounded gonostylus of trizonatum males (Figures 234).

DISCUSSION.—Lasioglossum trizonatum (Cresson, 1874), here considered a species group, has long been a source of confusion for bee taxonomists because of its extreme abundance and high levels of structural and color variability. Variation in leg color led J.C. Crawford in 1907 to

recognize L. mellipes from cismontane southern California. This species has bright yellowish orange hind tarsi unlike the darkly pigmented legs of other trizonatum forms. However, this color difference appears to be clinal, with structurally similar specimens from Washington and Oregon having dark legs. As early as 1941, Cockerell stated that "Timberlake considers this [L. mellipes] a race of H. trizonatus Cresson." Another obvious source of variation is the head length of females with length/width ratios ranging from 0.88 to 1.04. Unfortunately, these differences in head length are often subtle and difficult to work with. Compounding the problem is that the genitalia of associated males appear to be identical and the type of Halictus trizonatus is apparently lost (Cresson, 1916, mentions that he could not find his own type).

Early in my studies I noticed that certain females from the Sierra Nevada of California, herein described as L. anhypops, were unique among trizonatum forms in lacking an acarinarium on the anterior surface of tergum I (Figure 85 vs. Figures 693, 711). Only 2.7% of the female L. anhypops examined carried mites, which sharply contrasts with the infestation levels of other forms (68.0% to 82.4%). Females of this species also have the lateral edge of tergum II conspicuously excavated (Figure 154). The shape of this tergal edge proved to be a useful character in delimiting other trizonatum forms. Females of L. egregium have a straight tergal edge (Figure 116); that of L. mellipes is evenly sinuate (Figure 117); and that of L. trizonatum sharply to moderately excavated (Figure 115).

Because of this structural and biological variation (association with mites) and apparent lack of intermediate forms, I have recognized one trizonatum form as a new species (L. anhypops) and have elevated one name from synonymy (L. egregium). As mentioned above, L. anhypops females are easily recognized by their lack of an acarinarium and the sharply excavated edge of tergum II. Many males of this species are unique in having darkly pigmented clypeal surfaces, lacking an apical yellow maculation. Not all spec-

imens lack the clypeal maculation and these are best recognized by the very short, inconspicuous hairs on sternum V (Figure 676).

Lasioglossum egregium, described by Vachal from Washington state and British Columbia, is very distinctive in having the female tergal edge virtually straight (Figure 63). Males associated with this species are unique in having extremely elongate, erect lateral hair tufts on sternum V (Figure 687). These hairs on sternum V are subequal in length to those on sternum IV and together form a continuous, uninterrupted hair fringe (where erect lateral hair tufts occur in other trizonatum forms, the hairs on sternum V are noticeably shorter than those of the preceding segment).

Although the pale leg coloration fails as a diagnostic character for all L. mellipes females, the lateral edge of their tergum II is characteristically sinuate (Figure 61). Males of this species are unique among trizonatum males in having yellowish orange hind tarsi throughout their range. The vestiture on sternum V of these males is highly variable, superficially suggesting that two species are involved. One form, having elongate, erect lateral hair tufts on sternum V (Figure 701), is found from coastal northern California south to cismontane southern California. The other male form has relatively short hairs on sternum V and lacks lateral hair tufts, but has a conspicuous median rosette of erect hairs (Figure 702). This male is found in Washington, southern Oregon, and northern California through the Sierra Nevada. Where the two forms occur sympatrically along the central Californian coastline, a confusing array of apparent intermediate specimens is found. Because of this apparent intermediacy I am not recognizing two distinct species; however, this possibility should be considered in future studies. Most helpful for resolution of this problem would be the successful rearing of known nest mates of both sexes, especially from the San Francisco Bay area of California.

As previously mentioned, the type of *Halictus* trizonatus is apparently lost. Cresson's only men-

tion of his original type material was "one specimen collected in Nevada by Dr. H.C. Yarrow." Occurring in most western states and especially abundant in Colorado are females with conspicuously elongate heads, acarinaria on the anterior surface of tergum I, and moderately to strongly excavated lateral edges of tergum II. In an effort to stabilize the use of the name *trizonatum*, I herein designate one of these females, also from Nevada, as the neotype of *H. trizonatus*.

As presently construed, L. trizonatum is highly variable; future work may show more than one species to be involved. Females have the lateral edge of tergum II sharply excavated (Figure 115) to only moderately but abruptly excavated. Whereas the heads of all L. trizonatum females are conspicuously elongate, the heads of those females occurring in Mono County, California, are even longer (length/width ratio  $\bar{x} = 1.02$ , vs. 0.93-0.98 for all other females). Males associated with this species show comparable variation, most notably the presence or absence of antennal tyli (Figure 714). The males of L. trizonatum from Mono County usually have conspicuous tyli and very short, inconspicuous vestiture on sternum V. Many other males, occurring throughout the West, have tyli and moderately elongate, erect lateral hair tufts on sternum V. Finally, there are widespread males that lack tyli and have short sternal hairs similar to those of the Mono County males. So much variability among these forms occurs that they cannot be reliably and consistently separated at present. This variation obviously warrants further study (see species treatment of L. trizonatum for details and distribution of male forms).

As for the *forbesii* complex, the present treatment of the *trizonatum* species group must be considered to be preliminary. Most helpful would be biological studies in areas of sympatry and the rearing of males and females from the same nests.

## 44. Lasioglossum anhypops, new species

FIGURES 17, 85, 154, 669-681

TYPE MATERIAL.—The female holotype of L. anhypops is the property of the California Insect

Survey, University of California, Berkeley, but is on loan deposit to the California Academy of Sciences in San Francisco. The specimen is in excellent condition and is labeled

Echo Lake El Dorado Co.[unty] Cal.[ifornia] VII[July]-9 1954/W.W. Middlekauff Collector/HOLOTYPE Lasioglossum anhypops R.J. McGinley [red label].

One hundred paratypes (732, 276)listed in the "Specimens Examined" section are designated.

ETYMOLOGY.—The specific epithet is a reference to the uniqueness of this species among members of the *trizonatum* group in being only rarely associated with phoretic mites (hypopodes).

DISTRIBUTION (Figure 669).—Lasioglossum anhypops occurs from southern British Columbia, including Vancouver Island, south through the Cascade Range of Oregon and through the Sierra Nevada to Los Angeles and San Bernardino counties in California. To the east, specimens have been taken in central Montana, Wyoming, and south to northern Utah. The occur-

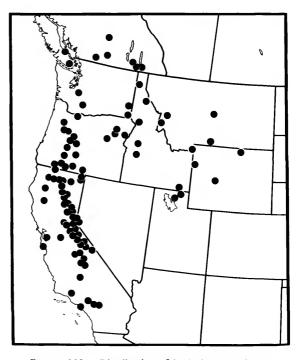

FIGURE 669.—Distribution of Lasinglossum anhypops.

rence of specimens in the San Francisco Bay area is unusual, but a few accurately determined specimens have been observed.

DIAGNOSIS.—The strongly, often sharply excavated lateral edge of tergum 1I (Figure 154) and the lack of an acarinarium on the anterior surface of tergum 1 (Figure 85) will distinguish females of L. anhypops from all other known species of Lasioglossum. Females of L. trizonatum have a similar tergal edge but have an acarinarium (Figure 711) and much longer heads (Figure 709, length/width ratio  $\bar{x}=0.97, n=25 \text{ v}$ . Figure 670, length/width ratio  $\bar{x}=0.93, n=15$ ). Lasioglossum coriaceum females also have a strongly excavated tergal edge but have an acarinarium (Figure 72) and occur only in eastern United States (Figure 353).

Many males of *L. anhypops* can be recognized by their flat clypeal surfaces, which lack an apical yellow maculation. In other species where the clypeus is entirely dark, the clypeal surface is broadly rounded (e.g., *L. pacificum*, *L. olympiae*). Males having the yellow clypeal maculation can be very difficult to diagnose, being best recognized by the very short, inconspicuous vestiture on sternum V (Figure 676).

DESCRIPTION.—FEMALE: (1) Length 8.2–10.1 mm ( $\bar{x} = 9.0$ , n = 15); (2) wing length 2.3–2.8 mm ( $\bar{x} = 2.6$ , n = 15); (3) abdominal width 2.5–3.0 mm ( $\bar{x} = 2.8$ , n = 15).

Structure: (4) Head elongate (Figure 670; length/width ratio 0.88-1.0,  $\bar{x}=0.93$ , n=15). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately its full length below lower margin of eyes; (10) surface with obscure median longitudinal sulcation present in most specimens. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 672; (27) distal keel moderately narrow, parallel-sided; (28) distal lateral projections well developed, triangular; (29) most fimbrial setae narrowly rounded apically, not sharply pointed.

(32) Pronotal lateral angle narrowly obtuse; (33) pronotal lateral ridge incomplete, inter-

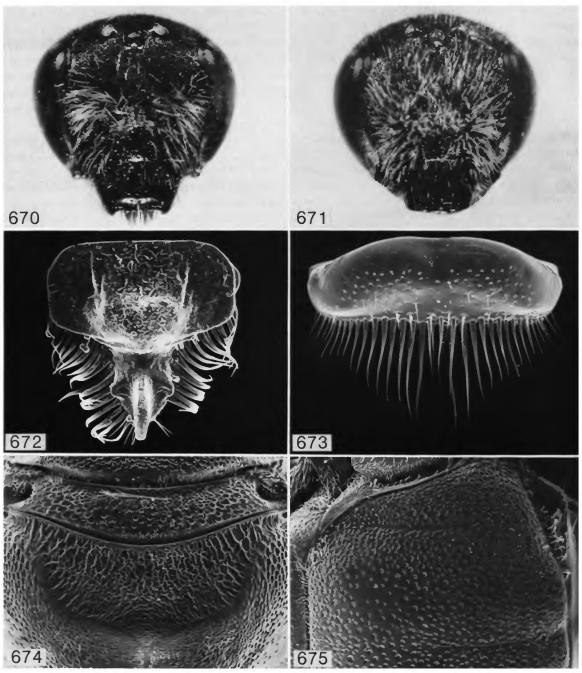

rupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.88 the length of scutellum and about 1.7 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin rounded; (43) propodeal triangle not defined laterally, evident medially as an inconspicuously V-shaped elevation without lateral rims; (44) lateral carinae extending at most to midpoint of posterior surface. (45) Tibial spur as in Figure 17.

(46) Lateral edge of metasomal tergum 1I strongly excavated, concave posteriorly, convex anteriorly with median area sharply angulated (Figure 154) or rounded (similar to Figure 115).

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming larger and less dense near antennae. (51) Supraclypeal area polished; (52) punctures separated by 1-2 times their width, becoming impunctate centrally. (53) Clypeus obscurely granulate basally, apical half polished; (54) punctures separated by their width or less basally, apical third sparsely punctate with large impunctate areas. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 675, punctures separated by their width or less laterally and anteriorly, much less dense centrally, punctures 2-3 times their width apart. (58) Scutellum somewhat sparsely punctate adjacent to median line, punctures 1-2 times their width apart. (63) Dorsal surface of propodeum (Figure 674) striolate laterally becoming finely ruguloso-striolate medially, striae reaching posterior margin; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (66) punctation fine, dense, punctures slightly less than their width apart.

Coloration: (71) Wing membrane mostly hyaline, very obscurely pigmented in marginal cell.

Vestiture: (74) Pubescence of head yellowish white. (75) Pubescence of thorax yellowish white; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hairs concolorous, pale yellowish brown. (78) Anterior hairs of metasomal tergum I yellowish white, (79) basal hair

FIGURES 670-675.—Lasioglossum anhypops: 670, female head; 671, male head; 672, female labrum; 673, male labrum; 674, female propodeum; 675, female mesoscutum.

bands of terga I1-1V white. (80) Acarinarium absent (Figure 85), elongate hairs scattered over anterior surface of tergum 1.

MALE: Similar to female except as follows: (1) length 6.7-8.5 mm ( $\bar{x} = 7.5$ , n = 15); (2) wing length 2.1-2.4 mm ( $\bar{x} = 2.2$ , n = 15); (3) abdominal width 1.8-2.2 mm ( $\bar{x} = 2.0, n = 15$ ). (4) Head as in Figure 671 (length/width ratio 0.87-0.96,  $\bar{x} = 0.93$ , n = 15). (5) Gena slightly wider than eye, (6) moderately produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. Labrum as in Figure 673; (24) distal process absent; (25) basal area depressed medially; (26) basal lateral depressions absent. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus polished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present or absent. (69) Flagellum entirely dark. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 676; (82) hairs on sternum IV moderately elongate, erect; (83) vestiture of sternum V mostly inconspicuous, with obscure median rosette of short hairs and small patch of moderately short, erect hairs near base.

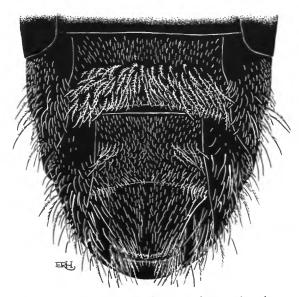

FIGURE 676.—Lasioglossum anhypops, male sternal vestiture.

Terminalia: Sterna VII-VIII similar to Figure 706; (85) sternum VIII with short, narrowly rounded median process. Genitalia as in Figures 677–680; (86) gonobase moderately elongate; (87) gonostylus moderately robust, narrowly rounded apically; (89) retrorse membranous lobe moderately slender; (90) volsella with prominent lateral lobe.

FLIGHT RECORDS (Figure 681).—Nearly all females of *L. anhypops* have been collected from May through October, with 82% of the records coming from June and July, with a peak in late June (northwestern records peak in early July). One female was taken in Lee Vining, Mono County, on 7 March 1933. The four female records from October were from San Bernardino and Shasta counties, California, and Whitman County, Washington. Males have been taken from July through September, with 56% of the records from August.

FLOWER RECORDS.—Females (77): Hydrophyllaceae 21%; Ericaceae 10%; Salicaceae 9%; Scrophulariaceae 9%. Males (64): Compositae 77%. Total: 141 in 21 families, 37 genera as follows:

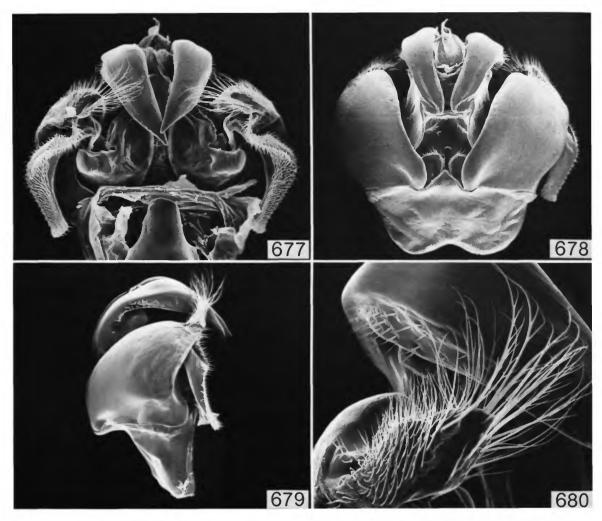

Achillae 19; Agastache 19; Apocynum 18; Arctostaphylos 89; Aster 29, 68; Astragalus 19; Chrysopsis 68; Chrysothamnus 19, 118; \*Epilobium 28; Erigeron 28; Eriogonum 29, 28; \*Erysimum 4(1)9; Geranium 18; Gutierrezia 38; Haplopappus 38; Helenium 18; Horkelia 19; Iris 29; Juniperus 68; Lonicera 39; Lupinus 19; Mentzelia 18; Montia 29; \*Pentstemon 7(1)9; \*Phacelia 16(14)9; Phlox 29; Polemonium 19; Pontentilla 49, 78; Prunus 39; \*Purshia 1(1)9; Ranunculus 19; \*Ribes 4(2)9; Rubus 19; Salix 79; Senecio 28; Solidago 108; \*Taraxacum 1(1)9.

MITE ASSOCIATES.—Although females of *L. anhypops* lack an acarinarium, a few females did have hypopodes on the anterior surface of tergum I. These amounted to only 15 out of 613 specimens examined, or 2.7%. The mites were attached to the tergal surface between the elongate hairs that cover tergum I. None of the 262 males of *L. anhypops* examined carried mites.

SPECIMENS EXAMINED.—Paratypes (739, 278).

# 45. Lasioglossm egregium (Vachal), new combination

FIGURES 31, 63, 682-694

Halictus egregius Vachal, 1904:476 [female].—Cockerell, 1905a:90 [key].—Crawford, 1906:303 [comparison to H. trizonatus].—Michener, 1951:1107 [synonymy with L. trizonatum].—Moure and Hurd, in press [lectotype designation].

Type Material.—The type material of *L. egregium* is deposited in the Naturhistorisches Museum, Vienna. Moure labeled one of Vachal's two females the lectotype in 1958 and has recently published this designation (Moure and Hurd, 1986). The lectotype is labeled

Brit.[ish] Columb[ia] Yale 189[year not indicated]/egregius det. J. Vachal [handwritten by Vachal?]/H.[alictus] § egregius Vach[al] [handwritten by Vachal?]/Lectotype egregius § Vach[al] det.[ermined by] J.S. Moure 1958 [handwritten by Moure].

The specimen is missing the right rear wing but is otherwise in excellent condition and clearly shows the diagnostic straight lateral edge of tergum II (Figure 63). I have attached a yellow paralectotype label to Vachal's other type specimen.

DISTRIBUTION (Figure 682).—Lasioglossum egregium has been collected in British Columbia, Alberta, Manitoba, and every American state west of the 104th meridian.

DIAGNOSIS.—Females of L. egregium can be

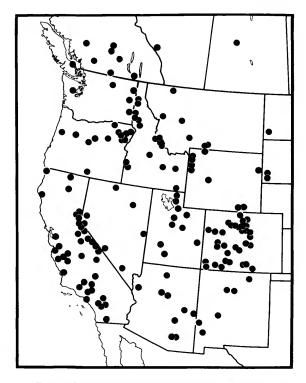

FIGURE 682.—Distribution of Lasioglossum egregium.

recognized by the straight lateral edge of tergum II (Figure 63). Males have elongate heads (Figure 684, length/width ratio  $\bar{x} = 0.98$ , n = 15) and extremely elongate, erect lateral hair tufts on sternum V (Figure 687). The lateral hair tufts on sternum V are as long as those on the preceeding segment and together form a continuous, uninterrupted hair fringe. Other males occurring in western United States and Canada that have erect lateral hair tufts on sternum V are L. mellipes, which have yellowish orange hind tarsi, certain L. trizonatum males that have antennal tyli (Figure 714) and noticeably shorter hairs on sternum V than on IV, and L. athabascense, which have a shorter head (Figure 289, length/ width ratio  $\bar{x} = 0.95$ , n = 20) and a rounded clypeal surface (clypeal surface flat in L. ergregium).

DESCRIPTION.—FEMALE: As described for L. anhypops except as follows: (1) Length 8.8-10.8

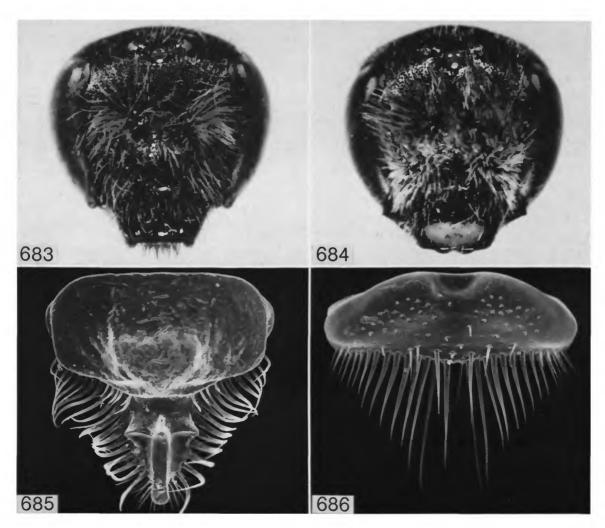

mm ( $\bar{x} = 9.7$ , n = 15); (2) wing length 2.6–3.2 mm ( $\bar{x} = 3.0$ , n = 15); (3) abdominal width 2.8–3.3 mm ( $\bar{x} = 3.0$ , n = 15).

Structure: (4) Head elongate (Figure 683; length/width ratio 0.92-1.0,  $\bar{x}=0.96$ , n=15). (9) Clypeus projecting approximately 0.88 of its length below lower margin of eyes.

(46) Lateral edge of metasomal tergum II virtually straight (Figure 63).

Vestiture: (75) Pubescence of thorax mostly

yellowish white, white on pronotal lateral angle, pronotal lobe and metanotum. (80) Acarinarium present (Figure 693), a moderately large glabrous area at base of tergum I, surrounded laterally by elongate fringe hairs, which lack a sharply delimited border; acarinarial surface often with some scattered hairs; dorsal opening of acarinarium moderately wide, not sharply delimited, width slightly less than width of lateral hair fringe as seen in dorsal view.

FIGURES 683-686.—Lasioglossum egregium: 683, female head; 684, male head; 685, female labrum; 686, male labrum.

MALE: As described for *L. anhypops* except as follows: (1) length 7.2–9.8 mm ( $\bar{x}$  = 7.9, n = 15); (2) wing length 2.2–2.7 mm ( $\bar{x}$  = 2.5, n = 15); (3) abdominal width 1.8–27.7 mm ( $\bar{x}$  = 2.1, n = 15). (4) Head elongate (Figure 684); length/width ratio 0.92–1.0 ( $\bar{x}$  = 0.98, n = 15). (68) Clypeal maculation present.

Vestiture: Sternal vestiture as in Figure 687; (82) hairs on sternum IV erect, moderately elongate medially, gradually becoming longer laterally, forming conspicuous lateral erect hair tufts; (83) vestiture of sternum V similar to that of sternum IV (median hairs on sternum IV shorter than those on V).

FLIGHT RECORDS (Figure 694).—Females of L. egregium have been collected in every month from February through November, with 65% of the records coming from June and July, with a peak in late June. Males have been taken from April to October, with 73% of the records from August and September.

FLOWER RECORDS.—Females (116): Scrophulariaceae 21%; Compositae 18%; Rosaceae 10%. Males (44): Compositae 93%. Total: 160 in 20 families, 47 genera as follows:

Apocynum 19; Arctium 18; Arctostaphylos 29; Aster 19, 238 (15 labeled Aster and Grindelia); \*Baccharis 1(1)9; Barbarea 19; Beloperone 19, \*Brassica 1(1)9; Carduus 18; Centaurea 38;

## 46. Lasioglossum mellipes (Crawford)

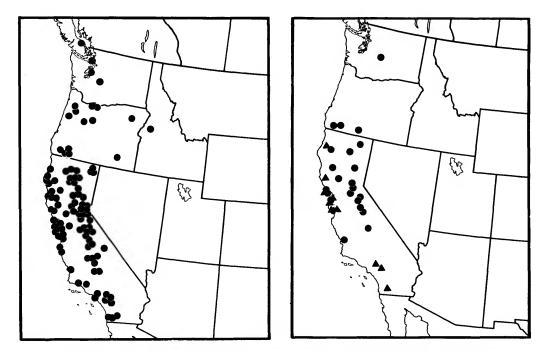

FIGURES 40, 61, 695-707

Halictus mellipes Crawford, 1907:190 [female].—Cockerell, 1941:343 [locality records, possible taxonomic status]. Lasioglossum mellipes.—Michener, 1951:1107 [Nearctic catalog].—Moldenke and Neff, 1974:52 [locality and flower records].—Hurd, 1979:1957 [Nearctic catalog].—Hurd et al., 1980:28, 65 [flower records].

TYPE MATERIAL.—The female holotype of L. mellipes is in the National Museum of Natural History, Smithsonian Institution. The specimen is in excellent condition and is labeled

Mts. [Mountains] near Claremont [Los Angeles County] Cal.[ifornia] Baker/[collected from] Ribes [handwritten/5051 [handwritten]/? Type No. 12036 U.S.N.M. [red label/Halictus mellipes? Type Cwfd [Crawford] [handwritten].

DISTRIBUTION (Figures 695, 696).—Lasioglossum mellipes occurs from Vancouver Island through Washington, Idaho, Oregon, and California to San Diego County. Michener (1951)

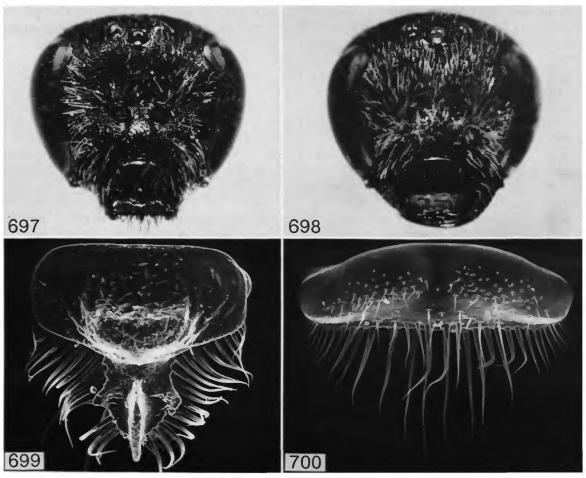

FIGURES 695, 696.—Distribution of Lasioglossum mellipes. Left: 695, females. Right: 696, males, short-haired forms (circle) and long-haired forms (triangle); see text for details.

reported this species from Baja California and this record has been restated by Hurd (1979) and Hurd et al. (1980). Although the occurrence of *L. mellipes* in Mexico is likely, I have not seen any specimens of this species taken south of the Mexican border.

DIAGNOSIS.—The characteristically sinuate lateral edge of tergum II (Figure 61), presence of an acarinarium on the anterior surface of tergum I (similar to Figure 693), and the yellowish orange mid and hind tarsi of most specimens will separate females of L. mellipes from other Lasioglossum species. Leg color appears to vary clinally with specimens from Oregon and Washington having entirely dark legs and those from San Bernardino and Los Angeles counties in California (the type-locality of L. mellipes) with pale mid tarsi, hind tarsi and hind tibiae. The hind tibiae of specimens from more northern California counties are mostly darkly pigmented with high levels of variation in color pattern occurring. Leg color also varies in the females of L. anhypops, but their lack of an acarinarium and their strongly excavated tergal II edge (Figure 154) will distinguish them from L. mellipes.

Males of L. mellipes can be recognized by their yellowish orange tarsi. As mentioned in the introductory remarks to the trizonatum group, the vestiture of sternum V is highly variable, with that of one male form having elongate, erect lateral hair tufts (Figure 701) and another having a conspicuous median rosette of erect hairs (Figure 702), with apparent intermediates occurring along the central California coastline. Other Lasioglossum males having pale legs in western United States are L. lampronotum and L. titusi, both of which have conspicuously short heads (Figures 487, 633); L. channelense, known only from the California Channel Islands and having a virtually complete pronotal lateral carina (obviously interrupted in the trizonatum males) and a very wide gena that exceeds the width of the compound eye as seen in lateral view (subequal in trizonatum males); and males of L. paraforbesii,

FIGURES 697-700.—Lasioglossum mellipes: 697, female head; 698, male head; 699, female labrum; 700, male labrum.

which lack a conspicuous hair pattern on sternum V (Figure 416) and occur west only to Idaho and Utah (Figure 406).

**DESCRIPTION.**—FEMALE: As described for *L. anhypops* except as follows: (1) Length 8.7-10.3 mm ( $\bar{x}=9.5$ , n=15); (2) wing length 2.6-3.0 mm ( $\bar{x}=2.8$ , n=15); (3) abdominal width 2.7-3.0 mm ( $\bar{x}=3.0$ , n=15).

Structure: (4) Head moderately elongate to elongate (Figure 697; length/width ratio 0.88–1.0,  $\bar{x} = 0.93$ , n = 15). (9) Clypeus projecting approximately 0.94 of its length below lower margin of eyes.

(46) Lateral edge of metasomal tergum II evenly sinuate (Figure 61).

Sculpture: (51) Supraclypeal area mostly polished, obscurely granulate laterally (52) punctures separated by their width or less basally, less dense centrally, punctures separated by 1–2 times their width. (53) Clypeus polished; (54) punctation nearly uniform basally, punctures separated by their width or less, apical one-third virtually impunctate. (63) Dorsal surface of propodeum finely striolate only over basal half, posterior half relatively smooth with obscure rugulae.

Coloration: (71) Wing membrane light yellowish brown, pigmentation moderately heavy at base of marginal cell, membrane becoming clearer towards apex. (72) Unlike most species, many specimens with mid and hind tarsi and in some specimens hind tibiae yellowish orange (see above diagnosis).

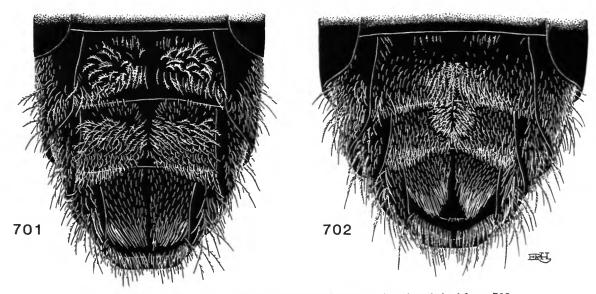

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax mostly pale yellowish brown, white on pronotal lateral angle, pronotal lobe and metanotum. (78) Anterior hairs on metasomal tergum I pale yellowish brown. (80) Acarinarium present (similar to Figure 693), a large glabrous area at base of tergum I, surrounded laterally by elongate fringe hairs that lack a sharply delimited border; opening of acarinarium moderately wide, not sharply delimited, width subequal to width of lateral hair fringe as seen in dorsal view.

MALE: As described for *L. anhypops* except as follows: (1) length 7.8–9.2 mm ( $\bar{x} = 8.4$ , n = 27); (2) wing length 2.3–2.9 mm ( $\bar{x} = 2.5$ , n = 27); (3) abdominal width 2.0–2.7 mm ( $\bar{x} = 2.2$ , n = 27). (4) Head as in Figure 698 (length/width ratio 0.87–1.0,  $\bar{x} = 0.96$ , n = 27). (68) Clypeal

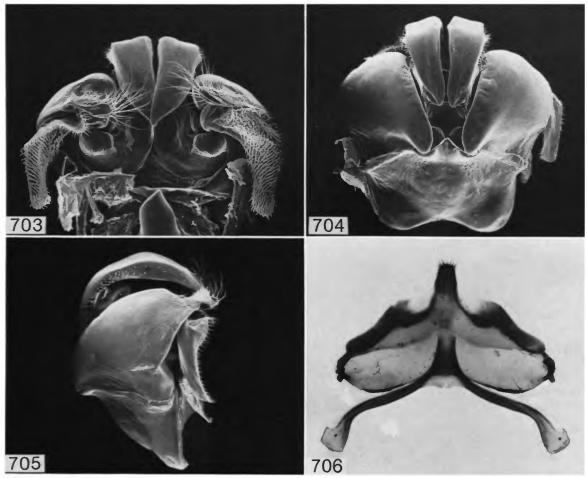

maculation present. (69) Flagellum yellowish orange ventrally, contrasting with dark dorsum. (72) Tarsi yellowish orange, contrasting with dark tibiae.

Vestiture: Sternal vestiture as în Figures 701, 702; (82) hairs on sternum IV moderately elongate, erect; (83) vestiture of sternum V variable, median rosette of erect hairs present (sometimes conspicuously developed), hairs laterad of rosette short, inconspicuous or gradually becoming longer and noticeable towards lateral margin of sternum (see "Diagnosis" section).

FLIGHT RECORDS (Figure 707).—Females of L. mellipes have been taken in all months except November and January. Most specimens have been taken in late June, with 73% of the records coming from May through July. The two females taken in October were from Alameda County, California, and Harney County, Oregon. The female taken in December was also from Alameda County. Males of L. mellipes have been collected from late April through September, with most records from early July. There does not appear to be a significant difference in the flight periods of the two forms of L. mellipes

FIGURES 701, 702.—Lasioglossum mellipes, male sternal vestiture: 701, long-haired form; 702, short-haired form.

FIGURES 703-706.—Lasioglossum mellipes, male: 703, genitalia, ventral view; 704, same, dorsal view; 705, same, lateral view; 706, sterna VII-VIII.

males other than that the males with short hairs on sternum V possibly fly later than the males with long sternal hairs, reflecting the occurrence of the former form in the Sierra Nevada of California.

FLOWER RECORDS.—Females (108): Scrophulariaceae 23%; Compositae 10%; Cruciferae 8%; Ranunculaceae 7%. Males (12): Compositae 58%. Total: 120 in 26 families, 43 genera as follows:

Apocynum 16; Aralia 16; Arctostaphylos 49; Asclepias 19; Asculus 19; Baccharis 19; \*Brassica 9(7)9; \*Calochortus 3(2)9; \*Ceanothus 1(1)9; \*Chamaebatia 5(5)9; Chrysothamnus 59;

#### 47. Lasioglossum trizonatum (Cresson)

FIGURES 57, 708-718

Halictus trizonatus Cresson, 1874:101 [female].—Dalla Torre, 1896:87 [World catalog].—Crawford, 1906:303 [locality record, taxonomic notes].—Cockerell, 1906:293 [locality and taxonomic notes]; 1908:120 [locality and flower records].

Lasioglossum trizonatum.—Michener, 1951:1107 [Nearctic catalog].—Linsley et al., 1963:42 [locality and flower records].—Moldenke and Neff, 1974:59 [flower records].—Hurd, 1979:1598 [Nearctic catalog].

Type Material.—In a review of his types, Cresson (1916) indicated that the female holotype of Halictus trizonatus could not be located. A recent search for this specimen was also unsuccessful. Because of the taxonomic confusion concerning forms in the trizonatum group, it is necessary to stabilize the use of this name by designating a neotype. Cresson's description was generalized and does not clearly indicate which trizonatum form he had before him. However, he does mention that the specimen was from Nevada (unspecified locality) and that it had black legs. Both the locality and leg color indicate that Cresson did not have a specimen of L. anhypops or L. mellipes. Lasioglossum egregium occurs in Nevada and has black legs; however, this name is stabilized by the availability of Vachal's type material. 1 therefore choose as a neotype for L. trizonatum a specimen, also from Nevada, that is representative of a widespread trizonatum form with black legs that is in need of a stabilized name (see introductory remarks for the trizonatum group and following diagnosis for comparison to other trizonatum forms). The neotype is the property of the California Insect Survey, University of California, Berkeley, but is on loan deposit to the California Academy of Sciences in San Francisco. The specimen is in good condition and is labeled

Nev[ada]:Eldo Co.[unty], Eslope, Spruce Mtn.[Mountain] V1 [June]-26-[19]56/W.C. Russell Collector/NEOTYPE Halictus trizonatus Cresson des.[ignated by] R.J. McGinley [handwritten on red label].

DISTRIBUTION (Figure 708).—Lasioglossum trizonatum has been collected in British Columbia (including Moresby Island), Alberta, and Manitoba and is widespread in western United States. In California it is found only along the eastern border of the Sierra Nevada and is very common

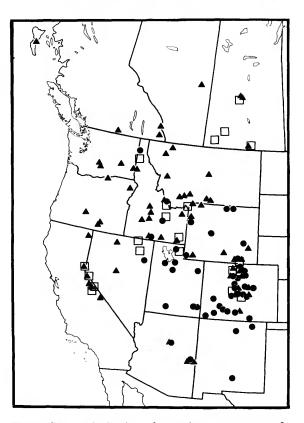

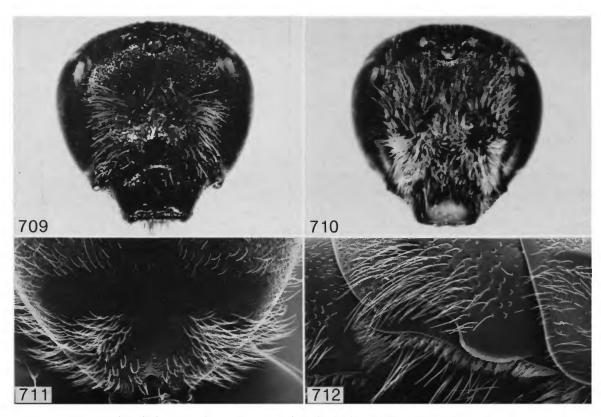

FIGURE 708.—Distribution of Lasinglossum trizonatum: females with lateral edge of tergum 11 strongly sinuate (circle), females with edge moderately sinuate (triangle), males (open square).

in Mono County. Females having a very sharply excavated lateral edge of tergum Il have been most commonly collected in Colorado and Utah, whereas specimens with a more rounded tergal emargination are widespread.

DIAGNOSIS.—Females of *L. trizonatum* can be distinguished from other *trizonatum* forms by their conspicuously elongate heads (Figure 709, length/width ratio  $\bar{x} = 0.96-1.02$ ), acarinaria on the anterior surface of tergum 1 (Figure 711), and moderately to strongly excavated lateral edges of tergum 11 (Figure 115). *Lasioglossum anhypops* females have a similar tergal edge but have shorter heads (Figure 670, length/width  $\bar{x} = 0.93$ , n = 15) and lack acarinaria (Figure 85). Some females in Mono County with only mod-

FIGURES 709-712.—Lasinglossum trizonatum: 709, female head; 710, male head; 711, female acarinarium at base of tergum 1; 712, lateral edge of female tergum II.

erately sinuate tergal edges can be differentiated from those of *L. mellipes* by their longer heads and black legs (hind tarsi and often hind tibiae usually yellowish orange in *L. mellipes*).

The males associated with L. trizonatum have conspicuously elongate heads (Figure 710, length/width ratio  $\bar{x}=1.02$ ) but are highly variable, possibly indicating that more than one species is involved. Most males are unique among Lasioglossum species in having antennal tyli (differentiated, oval areas on flagellomeres having only plate sensilla and lacking peg sensilla, Figures 714, 715). Most males with tyli have moderately elongate, erect lateral hair tufts on sternum V (Figure 713), but those from Mono County have very short, inconspicuous sternal hairs. Many males with conspicuously elongate

heads have short sternal hairs similar to the Mono County forms but lack antennal tyli. I have seen specimens with only weakly differentiated tyli and therefore hesitate in recognizing the "tyli" and "non-tyli" forms as being distinct.

DESCRIPTION.—FEMALE: As described for *L. anhypops* except as follows: (1) Length 8.4–11.5 mm ( $\bar{x}=9.5,\ n=25$ ); (2) wing length 2.5–3.1 mm ( $\bar{x}=2.8,\ n=25$ ); (3) abdominal width 2.6–3.3 mm ( $\bar{x}=2.9,\ n=25$ ).

Structure: (4) Head very elongate (Figure 709; length/width ratio 0.92-1.04,  $\bar{x}=0.97$ , n = 33). (7) Supraclypeal area evenly rounded, (8) moderately protuberant.

(46) Lateral edge of metasomal tergum II similar to that of *L. anhypops* but differing from all other *trizonatum* forms in being strongly exca-

vated, sharply angulated (as in Figure 154) or rounded medially (Figure 115).

Coloration: (71) Wing membrane pale yellowish brown, becoming hyaline near apex.

Vestiture: (74) Pubescence of head white. (75) Pubescence of thorax white. (77) Hind tibial hairs pale yellowish brown. (80) Acarinarium present (Figure 711), a moderately large glabrous area at base of tergum I, surrounded laterally by elongate fringe hairs, which lack a sharply delimited border; acarinarial surface often with some scattered hairs; dorsal opening of acarinarium moderately wide, not sharply delimited, width slightly less than width of lateral hair fringe as seen in dorsal view.

MALE: As described for *L. anhypops* except as follows: (1) length 7.7–8.5 mm ( $\bar{x} = 8.1$ , n = 9); (2) wing length 2.1–2.6 mm ( $\bar{x} = 2.3$ , n = 9); (3) abdominal width 1.8–2.2 mm ( $\bar{x} = 2.0$ , n = 9). (4) Head as in Figure 710 (length/width ratio 1.0–1.05,  $\bar{x} = 1.02$ , n = 18). (68) Clypeal maculation present.

Vestiture: Sternal vestiture as in Figure 713; (82) hairs on sternum IV elongate, erect; (83) vestiture of sternum V variable, inconspicuous, median rosette of hairs present, hairs laterad of rosette erect, inconspicuous or becoming notice-

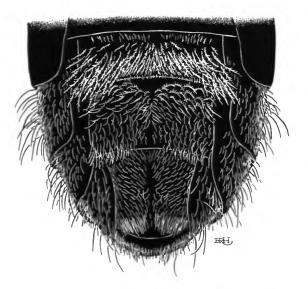

FIGURE 713.—Lasioglossum trizonatum, male vestiture.

ably elongate towards lateral margin of sternum (see "Diagnosis" section).

FLIGHT RECORDS (Figure 718).—Females of L. trizonatum have been collected from early April through September. Records of those from the southwestern region peak in early June, whereas those from the Northwest peak in late June.

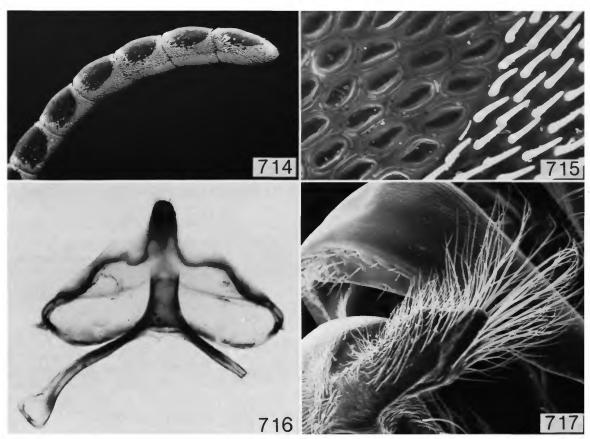

FLOWER RECORDS.—Females (96): Salicaceae 26%; Rosaceae 23%; Compositae 23%. Total: 96 in 12 families, 28 genera as follows:

Achillea 19; Agoseris 19; Anemone 19; Aster 19; Astragalus 19; Balsamorhiza 19; \*Barbarea 2(2)9; Chrysothamnus 29; Crepis 39; \*Erysimum 5(5)9; \*Frasera 1(1)9; Geum 39; Gilia 79; \*Heterotheca 1(1)9; \*Irish 5(3)9; \*Lappula 1(1)9; \*Penstemon 3(1)9; Phacelia 29; Phlox 19; Potentilla 19; \*Prunus 12(3)9; \*Purshia 2(1)9; Ribes 19; \*Rubus 4(2)9; \*Salix 25(4)9; Senecio 19; \*Taraxacum 7(4)9; Thermopsis 19.

SPECIMENS EXAMINED.—247 females with lateral edge of tergum II sharply excavated.

## 48. Lasioglossum tropidonotum, new species

FIGURES 58, 174, 300, 719-723

TYPE MATERIAL.—The female holotype is the property of the California Insect Survey, University of California, Berkeley, but is on loan deposit to the California Academy of Sciencies in San Francisco. The specimen is in excellent condition and is labeled

4 mi NW Ocosingo Chiapas, MEX. III [Mar]-8-1953/R.C. Bechtel E.I. Schlinger Collectors/[green unlabeled paper point]/LASIOGLOSSUM? det. G.C. Eickwort/HOLO-TYPE Lasioglossum tropidonotum R.J. McGinley [red label].

The male paratype listed in the "Specimens Examined" section is deposited in the collection of the University of California at Berkeley.

ETYMOLOGY.—The specific epithet is derived from the Latin *tropidos* (keel) and alludes to the distinctive, mesoscutal ridge that is unique to this species.

DISTRIBUTION (Figure 300).—Lasioglossum tropidonotum is known only from the female holotype and male paratype, both from the vicinity of Ocosingo in the state of Chiapas, Mexico.

DIAGNOSIS.—Both sexes of *L. tropidonotum* have a unique, median mesoscutal ridge near the anterior mesocutal margin (Figure 174). The female is also unique in having an extremely protuberant clypeus and having the frons and vertex covered with thick, distally recurved setae (Figures 174, 723). Furthermore, the female has sterna IV–V entirely covered by short, pale pubescence (found elsewhere only in *L. crocoturum* and *L. cercothrix*).

DESCRIPTION.—FEMALE: (1) Length 10.3 mm (n = 1); (2) wing length 2.6 mm; (3) abdominal width 3.0 mm.

Structure: (4) Head elongate (Figure 174; length/width ratio 0.96). (7) Supraclypeal area narrowly rounded ventrally, (8) protuberant. (9) Clypeus projecting approximately 0.76 of its length below lower margin of eyes; (10) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 along dorsal surface. Labrum virtually identical to that of L. circinatum, Figure 333; (27) distal keel moderately broad, widest basally; (29) distal lateral projections virtually absent, evident as obscure swellings; (29) most fimbrial setae blunt apically.

(32) Pronotal lateral angle narrowly obtuse: (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge narrowly rounded. (34) Mesoscutal lip not bilobed, (35) very weakly elevated from pronotum; unlike all other known Lasioglossum, the mesoscutum is elevated as a median longitudinal ridge near the anterior margin. (39) Dorsal surface of propodeum about 0.83 the length of scutellum and about 1.2 times the length of metanotum, (40) slightly depressed centrally, (41) posterior margin broadly rounded; (42) propodeal triangle weakly defined, evident medially as a very low V-shaped elevation without lateral rims; (43) lateral carinae extending at most to midpoint of posterior surface. (44) Tibial spur as in Figure 58.

(46) Lateral edge of metasomal tergum 11 weakly sinuate, nearly straight.

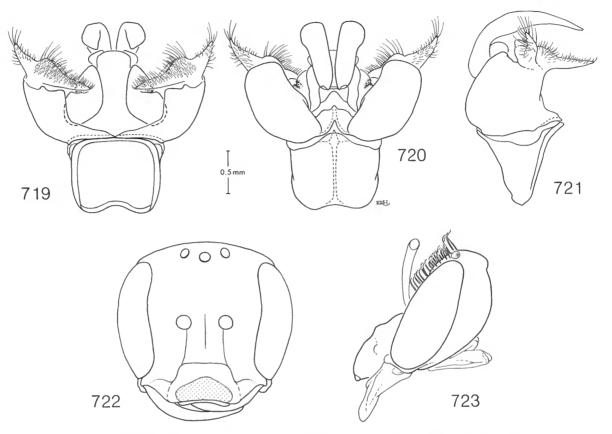

Sculpture: (47) Face weakly shiny, (48) densely and contiguously punctate below ocelli to antennae. (51) Supraclypeal area granulate, roughened ventrally; (52) punctures separated by their width. (53) Clypeus moderately granulate throughout; (54) punctures very dense, nearly contiguous over basal half, being larger and obscurely formed apically. (56) Mesoscutum moderately shiny; (57) punctation very similar to that of *L. circinatum*, Figure 335, obscurely dou-

bly-punctate, smaller punctures extremely dense, contiguous throughout, larger punctures 3–5 times their width apart (observable at 50 magnifications or more). (58) Scutellum contiguously punctate around margins, sparsely punctate centrally, punctures separated by 1–2 time their width. (63) Dorsal surface of propodeum (similar to Figure 334) nearly entirely smooth, weakly striolate laterally with very weak median striae confined to basal one-third; (64) surface extensively alveolated. (65) Metasomal tergum 1 shiny; (66) punctation fine, dense over most of dorsal surface, punctures slightly less than their width apart, becoming very sparse near and on anterior surface.

Coloration: (71) Wing membrane very weakly infuscated throughout.

Vestiture: (73) Unlike other species, vertex and frons covered with thick, recurved setae (simple recurved hairs are found in L. acarophilum, L. circinatum, L. pharum, and L. uyacicola but are not thick and pigmented as in L. tropidonotum); (74) pubescence of head mostly white, thickened setae on vertex and frons orangebrown. (75) Pubescence of thorax white: (76) mesoscutal hairs inconspicuous. (77) Hind tibial hair color differentiated, ventral and lateral hairs white, dorsal hairs brown. (78) Anterior hairs of metasomal tergum 1 white; (79) basal hair bands of terga 11-I11 yellowish white, terga 1V-V nearly entirely covered by yellowish, short pubescence. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum 1.

MALE: Similar to female except as follows: (1) length 7.5 mm (n = 1); (2) wing length 2.2 mm; (3) abdominal width 1.8 mm. (4) Head as in Figure 722 (length/width ratio 0.96). (5) Gena subequal to eye in width, (6) moderately produced posteriorly. (10) Clypeal surface noticeably depressed ventrally. Labrum similar to that of *L. asaphes* (Figure 277); (24) distal process absent; (25) basal area strongly depressed medially; (26) basal lateral depressions well developed. (30) Mandible moderately elongate, reaching just beyond opposing clypeal angle. (53) Clypeus pol-

FIGURES 719-723.—Lasioglossum tropidonotum: 719, male genitalia, ventral view; 720, same, dorsal view; 721, same, lateral view; 722, male head, frontal view; 723, female head, lateral view.

ished; (54) punctures well formed and dense basally, very fine and scattered over apical two-thirds becoming virtually impunctate medially near apical edge. (68) Clypeal maculation present. (69) Flagellum nearly entirely dark, only slightly paler ventrally than on dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: (82) Hairs on sternum IV erect, elongate, hairs becoming slightly longer laterally; (83) sternum V with median rosette of short erect hairs, becoming elongate and curled laterally.

Terminalia: Sterna VII-VIII virtually identical to those of L. acarophilum, Figure 256; (85) sternum VIII with sharply pointed median process. Genitalia as in Figures 719-721; (86) gono-

base elongate; (87) gonostylus moderately elongate, sharply pointed; (89) retrorse membranous lobe tapering distally to acute apex; (90) volsella lacking prominent lateral lobe.

FLIGHT RECORDS.—Both known specimens of Lasioglossum tropidonotum were collected in March.

REMARKS.—The holotype female had a nearly full scopal pollen load, and the unusual thick setae on the frons and vertex of the head were caked with pollen grains (these hairs in nearly all Lasioglossum species are plumose and similar to other hairs on the head). This suggests that the head is possibly used to collect pollen directly from the floral anthers with the pollen being

subsequently transferred to the hind legs for transport. If true, this method of pollen collecting and suggestion of possible floral specificity would be unique among Lasioglossum species. It should be noted that simple, recurved hairs on the frons and vertex are also found in L. acarophilum, L. pharum, L. circinatum, and L. uyacicola; however, the hairs here are very thin and do not appear thick enough to harvest pollen as suggested for L. tropidonotum.

SPECIMENS EXAMINED.—2 (19,18).

MEXICO. CHIAPAS: Ocosingo, 2 mi SE, 8 Mar 1953, E.I. Schlinger (1d; UCB), 4 mi NW, 8 Mar 1953, R.C. Bechtel, E.I. Schlinger (19, holotype; CAS).

# 49. Lasioglossum uyacicola (Cockerell)

FIGURES 59, 372, 724-731

Halictus uyacicola Cockerell, 1949:445 [female].
Halictus uyacensis Cockerell, 1949:445 [female].—Michener,
1954:40 [synonymy].

Lasioglossum uyacicola.—Michener, 1954:40 [redescription, male].

TYPE MATERIAL.—The female holotype of *Halictus uyacicola*, in the National Museum of Natural History, Smithsonian Institution, is in excellent condition. It is labeled

Uyaca Peak Feb[rurary] 9. [handwritten by Cockerell]/Honduras Cockerell Exp.[edition]/209. [handwritten by Cockerell]/Type No. 58484 USNM [red label]/Halictus uyacicola Ckll [Cockerell] TYPE [handwritten by Cockerell; nearly illegible due to running of ink].

An additional female in the Smithsonian collection has the same locality data as the type but was not designated as being a paratype by Cockerell.

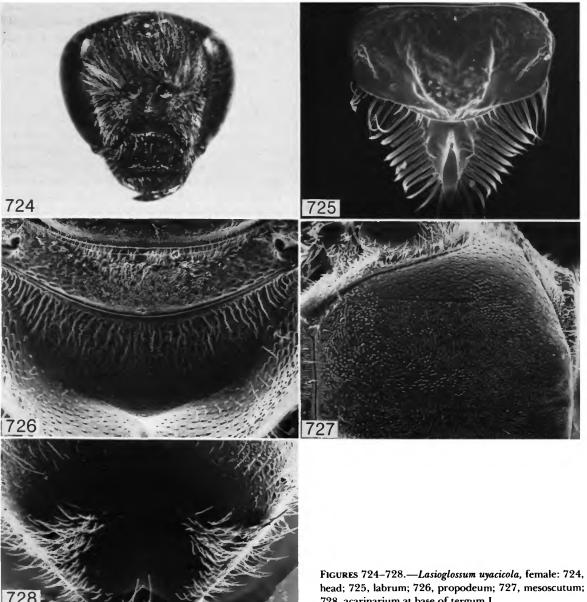

The female holotype of *Halictus uyacensis*, in the National Museum of Natural History, is also in excellent condition. The first three labels associated with this specimen are identical to those of the *H. uyacicola* type. The bottom two labels read

Type No. 58485 USNM [red label]/Halictus uyacensis Ckll [Cockerell] TYPE [handwritten by Cockerell; nearly illegible due to running of ink].

DISTRIBUTION (Figure 372).—Lasioglossum uyacicola is presently known from only 13 females and one male, which have been collected in Chiapas (Mexico), Honduras, Costa Rica, and Panama. The records from Panama represent the southernmost known limits of New World Lasioglossum.

DIAGNOSIS.—The doubly-punctate mesoscutum (Figure 727), presence of a large acarinarium (Figure 728), and the smooth posterior half of the propodeal surface (Figure 726) will distinguish Lasioglossum uyacicola from all other known New World Lasioglossum. Lasioglossum acarophilum is the most similar species to L. uyacicola and the two species occur sympatrically in Chiapas (Mexico). However, the mesoscutum of L. acarophilum is only obscurely doubly-punctate and is much more granuloso-punctate than that of L. uyacicola (Figures 251, 727). Furthermore, L. uyacicola has a relatively longer head (Figures 724, 246; length/width ratio 0.92-0.98,  $\bar{x} = 0.95$ vs. 0.88-0.96,  $\bar{x} = 0.91$ ). Lasinglossum bajaense, which is known only from the southern tip of Baja California, is similar but has a much shorter head (appearing slightly shorter than that of L. athabascense, Figure 228), relatively sparse mesoscutal punctation with the central punctures separated by their width or slightly more (punctures nearly contiguous in L. uyacicola), and has the posterior half of the propodeal dorsal surface polished and shiny (posterior half dull in L. uyacicola).

The smooth posterior half of the dorsal propodeal surface will distinguish the males of L. uyacicola, L. acarophilum, L. argutum, and L. tropidonotum from those of all other New World Lasioglossum. Lasioglossum argutum males can be quickly differentiated by the polished propodeal surface (posterior half dull in the other three species), and L. tropidonotum is unique in having a raised, median ridge on the anterior surface of the mesoscutum (Figure 174). Lasioglossum uyacicola and L. acarophilum males share a distinctive hair pattern on the posterior edge of sternum V (Figure 252) and along with L. tropidonotum are unique in having the retrorse membranous lobes

of the genitalia distally pointed (Figure 729). The gonostyli of L. uyacicola may be longer than those of L. acarophilum, but as yet the males of these two species cannot be reliably differentiated (they are known to be sympatric only in Chiapas, Mexico).

728, acarinarium at base of tergum I.

DESCRIPTION.—FEMALE: (1) Length 8.2-9.0 mm ( $\bar{x} = 8.6$ , n = 2); (2) wing length 2.4-2.6 mm ( $\bar{x} = 2.5$ , n = 2); (3) abdominal width 2.6-2.9 mm ( $\bar{x} = 2.75$ , n = 2).

Structure: (4) Head elongate (Figure 724; length/width ratio 0.92-0.98,  $\bar{x} = 0.95$ , n = 2).

(7) Supraclypeal area somewhat narrowly rounded, (8) protuberant. (9) Clypeus projecting approximately 0.87 of its length below lower margin of eyes; (10) surface with obscure median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 subequal to 2 in length along dorsal surface. Labrum as in Figure 725; (27) distal keel moderately broad, lateral edges bowed; (29) distal lateral projections weakly developed, rounded to narrowly rounded; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle moderately obtuse; (32) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge sharply edged. (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.75 the length of scutellum and about 1.4 times the length of metanotum, (41) slightly depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, evident medially as an inconspicuous V-shaped elevation with very low lateral rims, fading towards metanotum; (44) lateral carinae not reaching midpoint of posterior surface. (45) Tibial spur as in Figure 59.

(46) Lateral edge of metasomal tergum II only faintly sinuate, virtually straight.

Sculpture: (47) Face dull granulate, (48) doubly-punctate, smaller punctures nearly contiguous, larger punctures separated by 1-2 times their diameter. (51) Supraclypeal area extremely granulate; (52) uniformly punctate, punctures separated by 1-3 times their width. (53) Clypeus granulate basally, apical half polished; (54) punctures separated by their width or less. (56) Mesoscutum moderately shiny; (57) punctation as in Figure 727, obscurely doubly-punctate, smaller punctures dense, nearly contiguous throughout, larger punctures separated by 3-4 times their width. (58) Scutellum obscurely doubly-punctate, smaller punctures separated at most by their width, larger punctures scattered. (63) Dorsal surface of propodeum (Figure 726) striolate over basal two-thirds, posterior third smooth or with

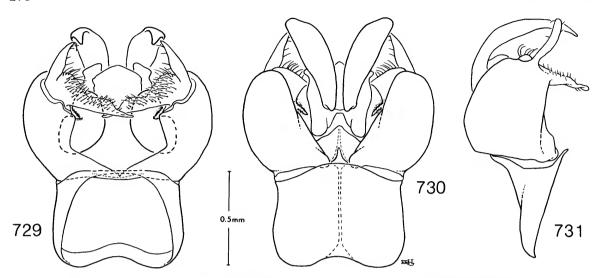

scattered, obscure rugulae; (64) surface alveolated. (65) Metasomal tergum I moderately shiny; (65) punctation very fine, extremely dense posteriorly, punctures nearly contiguous, becoming increasingly less dense towards impunctate anterior edge.

Coloration: (71) Wing membrane mostly hyaline, marginal cell and apex obscurely infuscated.

Vestiture: (73) Unlike most species, hairs between vertex and antennae conspicuously simple, recurved, contrasting with plumose hairs near antennae; (74) pubescence of head white. (75) Pubescence of thorax white; (76) mesoscutal hairs moderately dense, conspicuously plumose. (77) Hind tibial hair color differentiated, most hairs white, dorsal hairs brown to dark brown. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II-IV yellowish white. (80) Acarinarium present (Figure 728), a large, circular, glabrous area at base of tergum I, surrounded laterally and dorsolaterally by elongate fringe hairs; dorsal opening of acarinarium wide, opening slightly wider than width of lateral hair fringe as seen in dorsal view.

MALE: Similar to female except as follows: (1) length 8.8 mm (n = 1); (2) wing length 2.45 mm (n = 1); (3) abdominal width 1.9 mm (n = 1). (4) Head moderately elongate (length/width ratio 0.88, n = 1). (5) Gena slightly wider than eye, (6) moderately produced posteriorly. (10) Clypeal surface shallowly depressed ventrally. (24) Labral distal process absent; (25) basal area depressed medially; (26) basal lateral depressions conspicuously developed. (30) Mandible short, just reaching opposing clypeal angle. (53) Clypeus granulate basally, apical two-thirds weakly granulate, shiny; (54) punctures well formed, nearly contiguous basally, very fine and scattered over apical two-thirds. (68) Clypeal maculation present. (69) Flagellum light brown ventrally, contrasting with dark dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: (82) Hairs on sternum IV suberect, moderately elongate; (83) sternum V without conspicuous erect hairs, posterior sternal edge with straight-edged lateral hair lobes similar to

FIGURES 729-731.—Lasioglossum uyacicola, male genitalia: 729, ventral view; 730, dorsal view, 731. lateral view.

those of L. acarophilum (Figure 252).

Terminalia: (84) Sternum VII was not available for study; sternum VIII of the one available male was damaged (the median process was torn but the surrounding sternal edge indicates it is probably sharply pointed as in *L. acarophilum* and *L. tropidonotum*, Figure 256). Genitalia as in Figures 729–731; (86) gonobase elongate; (87) gonostylus very elongate, slender; (89) retrorse membranous lobe tapering to sharply pointed apex; (90) volsella lacking prominent lateral lobe.

FLIGHT RECORDS.—Females of *L. uyacicola* have been collected in most months from February to December. The one known male was collected in January.

#### 50. Lasioglossum xyriotropis, new species

FIGURES 504, 732

TYPE MATERIAL.—The holotype female of Lasioglossum xyriotropis is in the National Museum of Natural History, Smithsonian Institution. It is labeled

Pablillo, N.L. [Nuevo Leon] 23.V1 [June].1975 MEX.[ico]/ J.E. Gillaspy Collector/HOLOTYPE Lasioglossum xyriotropis R.J. McGinley [red label].

The left pair of wings are folded under the specimen and pierced by the insect pin but otherwise the holotype is in excellent condition. Six female paratypes, listed in the "Specimens Examined" section, are herein designated; five are in the Snow Museum, University of Kansas, and one in the Cornell University Collection.

ETYMOLOGY.—The Greek words *xyrion* (small razor) plus *tropis* (keel) allude to the complete and very sharply edged pronotal lateral carina, characteristic of this species.

DISTRIBUTION (Figure 504).—Lasinglossum

xyriotropis is presently known only from three Mexican states: Morelos, Nuevo Leon, and Tlax-cala.

DIAGNOSIS.—Very characteristic of L. xyriotropis is the clypeus that is conspicuously and almost entirely granulate (only the extreme apicolateral edges are polished). Also diagnostic is the following character combination: head moderately short; pronotal lateral carina conspicuously complete and sharply edged (Figure 732); membrane of forewing mostly hyaline, marginal cell and apex infuscated; mesoscutum nearly entirely granuloso-punctate, punctures slightly less dense on central posterior surface, where they are nearly contiguous but distinctly separated. Like L. manitouellum, to which it is very similar, L. xyriotropis lacks an acarinarium and has a noticeably shiny, striolate-rugulose dorsal propodeal surface. Lasioglossum manitouellum, unlike L. xyriotropis, has an incomplete pronotal lateral carina, a slightly shorter head (Figure 505), and a completely granuloso-punctate mesoscutum

FIGURE 732.—Lasioglossum xyriotropis, female pronotum, lateral view.

(punctures not distinctly separated posteriorly).

Lasinglossum xyriotropis is also similar to L. heterorhinum, with which it shares the complete pronotal lateral carina. The following characters of L. heterorhinum will differentiate these two species: apical half of clypeus polished; head conspiculously short (Figure 458; compare with Figure 505); forewing membrane not infuscated.

DESCRIPTION.—FEMALE: (1) Length 7.9–9.6 mm ( $\bar{x} = 8.8$ , n = 7); (2) wing length 2.4–2.7 mm ( $\bar{x} = 2.5$ , n = 7); (3) abdominal width 2.6–2.9 mm ( $\bar{x} = 2.7$  mm).

Structure: (4) Head moderately short (slightly longer than that of L. manitouellum, Figure 505; length/width ratio 0.92-0.96,  $\bar{x}=0.95$ , n=7). (7) Supraclypeal area evenly rounded, (8) moderately protuberant. (9) Clypeus projecting approximately 0.74 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli slightly shorter than distance between lateral ocellus and eye. (23) Flagellomere 1 slightly shorter than 2 along dorsal surface. (27) Labral distal keel broad in frontal view, somewhat spoon-shaped; (29) distal lateral projections virtually absent, evident as obscure lateral swellings; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle obtuse; (33, 34) pronotal lateral ridge conspicuously complete, sharply edged (Figure 732). (35) Mesoscutal lip weakly bilobed, (36) moderately elevated from pronotum. (40) Dorsal surface of propodeum about 0.80 the length of scutellum and about 1.3 times the length of metanotum, (41) depressed centrally, (42) posterior margin broadly rounded; (43) propodeal triangle weakly defined, median V-shaped elevation and lateral rims inconspicuous; (44) lateral carinae extending over jthree-quarters the length of posterior propodeal surface, nearly reaching posterior edge of dorsal surface.

(46) Lateral edge of metasomal tergum II sinuate.

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, only slightly less dense near antennae. (51) Supra-

clypeal area granulate throughout; (52) punctures separated by less than their width laterally, separated by 1-2 times their width centrally. (53) Clypeus nearly granulate throughout, polished only on extreme apicolateral edges; (54) punctures well formed basally, nearly contiguous, becoming larger and obscurely formed on apical half, separated by 1-2 times width. (56) Mesoscutum moderately shiny; (57) punctation similar to that in Figure 510, mostly granuloso-punctate, punctures nearly contiguous but distinctly separated on central posterior surface. (58) Scutellar punctures separated by their width centrally, nearly contiguous near edges (impunctate areas absent). (63) Dorsal surface of propodeum irregularly striate laterally, becoming ruguloso-striolate medially, striae and rugulae reaching posterior margin (similar to that in Figure 509); (64) surface obscurely alveolated (unlike most species except L. manitouellum, the propodeal dorsal surface is noticeably shiny). (65) Metasomal tergum I moderately dull; (66) punctation extremely fine, punctures virtually contiguous over most of doral surface.

Coloration: (71) Wing membrane nearly hyaline, lightly pigmented throughout with infuscated marginal cell and apex.

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax mostly pale yellowish brown, pronotal hairs white in some specimens; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hair color differentiated, outer brown hairs contrasting with mostly pale to yellowish white hairs. (78) Anterior hairs of metasomal tergum I white, (79) basal hair bands of terga II–IV yellowish white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

FLIGHT RECORDS.—One *L. xyriotropis* female was collected in April, the other six were taken in June.

MITE ASSOCIATES.—Although L. xyriotropis lacks an acarinarium, the one female from Morelos had numerous hypopodes clustered on the anterior surface of tergum I.

SPECIMENS EXAMINED.—79.

MEXICO, MORELOS: Cuernavaca, 4 mi NW, 12 Apr 1959, 7500 ft, H.E. Evans (12; CU). NUEVO LEON: Pablillo, 23 Jun 1975, J.E. Gillaspy (12 holotype; USNM). TLAXCALA: Apizaco, 8 mi W, 18 Jun 1961, 8200 ft, Univ. Kansas Mex. Exped. (52; KU).

## 51. Lasioglossum zonulum (Smith)

FIGURES 60, 205, 733-746

Halictus zonulus Smith, 1848:2171 [female, male].—Dalla
Torre, 1896:92 [World catalog; see for older literature].
—Atwood, 1933:451 [nests].—Brittain, 1933:94 [flower records].—Sandhouse, 1933:78 [synonymy].—Brittain and Newton, 1934:257, 260, 262 [locality and flower records].

Halictus similis.—Lovell, 1905:299 [misidentification of L. zonulum as evidenced by Lovell's 1908 synonymy of H. craterus].

Halictus craterus Lovell, 1908:35 [female, male; incorrectly identified as an Evylaeus].—Brittain and Newton, 1933:344 [locality and flower records]; 1934:262 [locality and flower records].—Sandhouse, 1933:78 [synonymy].—Covell, 1972:12 [lectotype, locality and flower records].

Halictus craternus.—Cockerell, 1916b:6 [lapsus calami]. Lasioglossum zonulum.—Michener, 1951:1107 [Nearctic catalog].—Evans and Lin, 1959:130 [predator, Philanthus gibbosus (Fabricius)].—Mitchell, 1960:346 [key, redescription].—Knerer and Atwood, 1962:163 [nests, locality and flower records].—Knerer, 1968:83 [presence in Aus-

tria].—Hurd, 1979:1958 [Nearctic catalog].

TYPE MATERIAL.—Smith based his descriptions of *Halictus zonulus* on a syntype series of more than one female and at least one male. I have examined one of the females of his type series, which is housed in the University Museum, Oxford. This female is in good condition; unfortunately, the associated label data was not recorded.

The female lectotype of *Halictus craterus* is in the National Museum of National History, Smithsonian Institution. It is labeled

Type No. 71566 U.S.N.M. [handwritten on red label]/224/Waldoboro [Lincoln County] Maine/1ris versicolor June 24–July 5 [handwritten]/Halictus craterus n. sp. Type § [handwritten]/Halictus craterus Lov. [ell] Holotype [handwritten on red label]/LECTOTYPE § Halictus craterus Lovell By C.V. Covell Jr. 1971.

The lecototype is in excellent condition; 28

**NUMBER 429** 

paralectotypes are also in the Smithsonian Collection.

DISTRIBUTION (Figure 733).—Like Lasioglossum leucozonium, L. zonulum is a holarctic species, widespread in Europe. In the New World it is found in Canada and the northern United States from Cape Breton Island, Nova Scotia west to Quadra Island off the east coast of Vancouver Island, British Columbia (Hurd, 1979, recorded this species west only to Minnesota). The northernmost record is two males from Cranberry Portage, Manitoba (54°36′ north latitude). Southernmost records include one female from Page County, Iowa, and one female from Madison County, Indiana.

DIAGNOSIS.—For diagnosis of female Lasioglossum zonulum see L. leucozonium diagnosis.

Males of L. zonulum can be easily recognized by the distinctive hair tufts on sternum VI and the well-developed posterolateral lobes of tergum VII (Figure 205, 744). Like the males of L. leucozonium, the clypeus is rounded (not flattened as in most male Lasioglossum) and the dorsal propodeal surface is strongly striate to rugose. In addition to differences in sternal vestiture, L. zonulum males differ from those of L. leucozonium in having completely dark legs (middle and hind

basitarsi yellow in the latter species).

DESCRIPTION.—FEMALE: (1) Length 8.5–10.5 mm ( $\bar{x} = 9.7$ , n = 15); (2) wing length 2.4–3.7 mm ( $\bar{x} = 2.6$ , n = 15); (3) abdominal width 3.0–3.5 mm ( $\bar{x} = 3.2$ , n = 15).

Structure: (4) Head elongate (Figure 734; length/width ratio 0.88-1.0,  $\bar{x}=0.94$ , n=15). (7) Supraclypeal area evenly rounded, (8) weakly protuberant. (9) Clypeus projecting approximately 0.81 of its length below lower margin of eyes; (11) surface without median longitudinal sulcation. (14) Distance between lateral ocelli subequal to distance between lateral ocellus and eye. (23) Flagellomere 1 longer than 2 along dorsal surface. Labrum as in Figure 736; (27) distal keel moderately broad in frontal view, gradually narrowing towards apex as in *L. leucozonium*; (29) distal lateral projections moderately well developed, weakly projecting; (29) fimbrial setae acutely pointed.

(32) Pronotal lateral angle narrowly obtuse, prominent with very well-developed dorsal ridge; (33) pronotal lateral ridge incomplete, interrupted by oblique lateral sulcus; (34) lower portion of lateral ridge inconspicuous, broadly rounded. (35) Mesoscutal lip rounded, not bilobed, (36) very strongly elevated from prono-

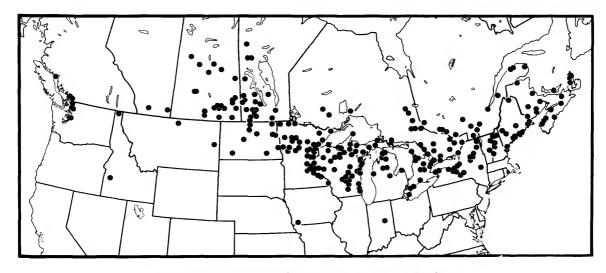

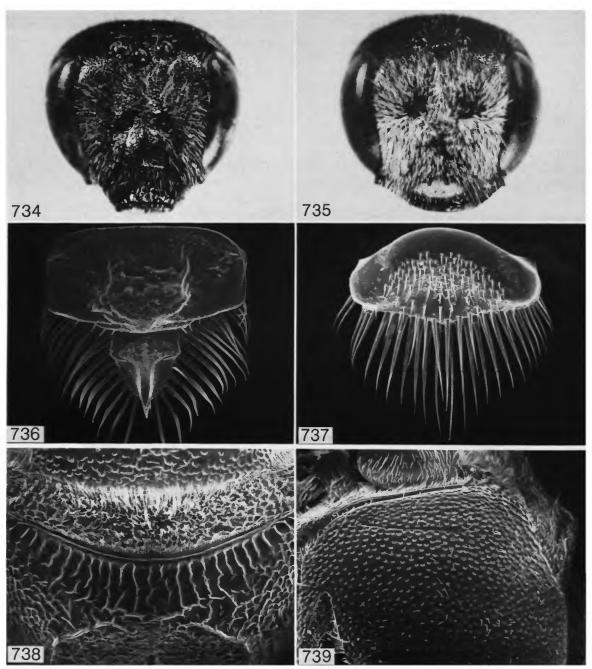

FIGURE 733.—New World distribution of Lasinglossum zonulum.

FIGURES 734-739.—Lasioglossum zonulum: 734, female head; 735, male head; 736, female labrum; 737, male labrum; 738, female propodeum; 739, female mesoscutum.

NUMBER 429 283

tum. (40) Dorsal surface of propodeum very short, about 0.53 the length of scutellum and slightly shorter than metanotum, (41) not depressed centrally, (42) posterior margin indistinctly truncated (lateral angles of dorsal surface gradually sloping from propodeal triangle); (43) propodeal triangle moderately well defined laterally; (44) lateral carinae nearly encircling posterior surface, interrupted dorsally. (45) Tibial spur as in Figure 60.

(46) Lateral edge of metasomal tergum II only faintly sinuate, virtually straight (similar to *L. leucozonium*).

Sculpture: (47) Face shiny, (48) densely punctate below ocelli, punctures contiguous, becoming somewhat punctuate below ocelli, punctures contiguous, becoming somewhat coarse near antennae. (51) Supraclypeal area extremely granulate; (52) uniformly and densely punctate, punctures separated by their width or less. (53) Clypeus obscurely granulate; (54) punctuation dense, nearly uniform, punctures separated by less than their width over basal two-thirds, separated by their width apicolaterally. (56) Mesoscutum shiny; (57) punctation as in Figure 739, punctures coarse, separated by their width or less laterally and anteriorly, becoming slightly less dense centrally, punctures 1-2 times their width apart. (58) Scutellar punctation coarse, similar to that of mesoscutum with widely separated impunctate areas. (63) Dorsal surface of propodeum (Figure 738) irregularly but very strongly striate with obscure transverse rugulae, striae reaching posterior margin; (64) surface smooth, not alveolated. (65) Metasomal tergum I shiny; (66) punctuation fine to very fine, moderately sparse posteriorly, punctures 1-1.5 times their width apart, very sparse anteriorly, punctures up to 4 times their width apart.

Coloration: (71) Wing membrane nearly hyaline, very lightly pigmented.

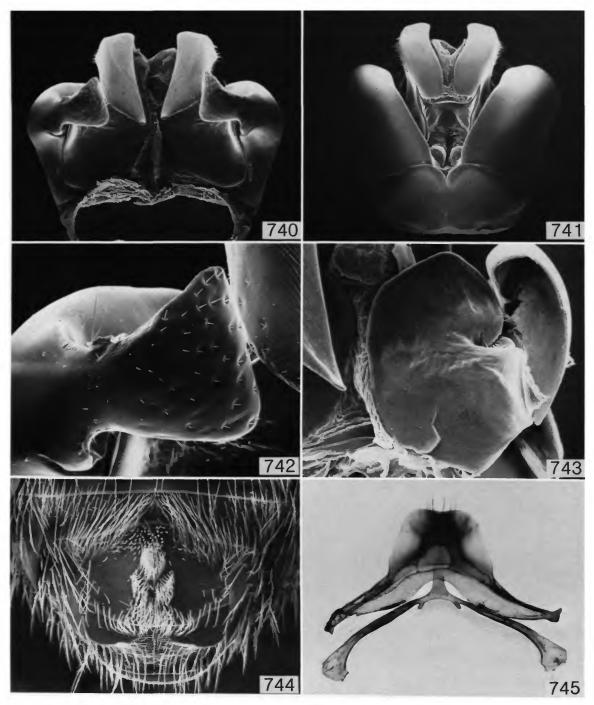

Vestiture: (74) Pubescence of head pale yellowish brown. (75) Pubescence of thorax white to pale yellowish brown; (76) mesoscutal hairs moderately dense and plumose. (77) Hind tibial hairs concolorous, yellowish brown. (78) Ante-

rior hairs of metasomal tergum I and (79) basal hair bands of terga II-IV white. (80) Acarinarium absent, elongate hairs scattered over anterior surface of tergum I.

MALE: Similar to female except as follows: (1) length 7.4-9.2 mm ( $\bar{x} = 8.5$ , n = 15); (2) wing length 2.1-2.6 mm ( $\bar{x} = 2.3$ , n = 15); (3) abdominal width 2.2-2.6 mm ( $\bar{x} = 2.5$ , n = 15). (4) Head as in Figure 735 (length/width ratio 0.89-1.0,  $\bar{x} = 0.93$ , n = 15). (5) Gena conspicuously wider than eye, (6) rounded, not produced posteriorly. (10) Clypeal surface broadly rounded. not flattened or depressed. Labrum as in Figure 737; (24) distal process weakly developed, rounded; (25) basal area rounded medially, not depressed; (26) basal lateral depressions very weakly developed; unlike other species, labral sensilla conspicuously dense and elongate. (30) Mandible moderately elongate, reaching slightly beyond opposing clypeal angle. (53) Clypeus weakly granulate, shiny; (54) punctation nearly uniform throughout, punctures separated by less than their width. (68) Clypeal maculation usually present, often reduced, more rarely absent. (69) Flagellum entirely dark or only slightly paler or venter than dorsum. (72) Tarsi dark, concolorous with tibiae.

Vestiture: Sternal vestiture as in Figure 744; (82) hairs on sterum IV elongate, erect, without noticeable pattern; (83) posterior half of sternum V with band of short, suberect hairs surrounding a bare spot at the midpoint of the posterior sternal edge; (84) unlike other New World Lasioglossum except L. leucozonium, sternum VI with very characteristic vestiture here characterized by a glabrous surface having a circular basal hair tuft adjacent to a posterior X-shaped hair patch.

Terminalia: Sterna VII-VIII as in Figure 745; (84) sternum VII somewhat reduced, slender (similar to that of L. leucozonium); sternum VIII without median process (like L. leucozonium sternal disc reduced, narrow). Genitalia as in Figures 740-743; (86) gonobase short; (87) gonostylus robust, flat, broadly rounded apically (like L. leucozonium, gonostylus with inconspicouous

FIGURES 740-745.—Lasioglossum zonulum, male: 740, genitalia, ventral view; 741, same, dorsal view; 742, gonostylus; 743, volsella; 744, sternal vestiture; 745, sterna VII-VIII.

setae); (88) retrorse membranous lobe absent; (90) volsella with conspicuous lateral flange but lacking prominent lobe.

FLIGHT RECORDS (Figure 746).—Lasioglossum zonulum females have been collected from early April through October, with most records from late June and late July. The six April records are 3 females, Moorhead, Minnesota, 27 Apr 1947; 2 females Ile Jesus, Quebec, 15 Apr 1906; 1 female, Hull, Quebec, 26 Apr 1938. Most males have been collected in late July but records range from June through October. The six males collected in June were all from Brandon, Manitoba, 13 June 1949.

FLOWER RECORDS.—Females (273): Compositae 40%; Leguminosae 14%; Rosaceae 14%; Cruciferae 8%. Males (54): Compositae 41%; Leguminosae 30%. Total: 327 in 18 families, 45 genera as follows:

# Identification of Figures in Keys

The following listing identifies the figures without legends utilized in the illustrated keys to *Lasioglossum* species.

## Key to Lasioglossum Females North of the Mexican Border

83, L. paraforbesii, acarinarium at base of tergum I. 84, L. colatum, acarinarium at base of tergum I. 85, L. anhypops, tergum l without acarinarium. 86, L. coriaceum, acarinarium. 87, L. transvorsum, mesoscutal anterior edge. 88, L. coriaceum, dorsal propodeal surface. 89, L. acarophilum, acarinarium. 90, L. acuminatum, mesoscutal anterior edge. 91, L. athabascense, dorsal propodeal surface. 92, L. forbesii, acarinarium at base of tergum I, dorsal view. 93, L. paraforbesii, acarinarium at base of tergum I, dorsal view. 94, L. acuminatum, acarinarium at base of tergum I. 95, L. forbesii, acarinarium. 96, head. 97, L. morrilli, head. 98, L. forbesii, acarinarium at base of tergum 1. 99, L. morrilli, acarinarium. 100, L. channelense, pronotum, lateral view. 101, L. mellipes, pronotum, lateral view. 102, L. trizonatum, head. 103, L. mellipes, head. 104, L. jubatum, head. 105, L. acarophilum, mesoscutum, 106, L. paraforbesii, mesoscutum, 107, L. acarophilum, dorsal propodeal surface. 108, L. paraforbesii, dorsal propodeal surface; 109, head; 110, dorsal propodeal surface; 111, acarinarium at base of tergum 1. 112, L. egregium, head; 113, dorsal propodeal surface; 114, acarinarium. 115, L. trizonatum, lateral edge of tergum II. 116, L. egregium, lateral edge of tergum 11. 117, L. mellipes, lateral edge of tergum 11. 118, L. paraforbesii, head. 119, L. jubatum, head. 120, L. bardum, acarinarium. 121, L. desertum, acarinarium. 122, L. bardum, dorsal propodeal surface. 123, L. desertum, dorsal propodeal surface. 124, L. titusi, dorsal view of vertex. 125, L. leucozonium, dorsal view of vertex. Dorsal propodeal surfaces: 126, L. titusi; 127, L. olympiae; 128, L. fuscipenne; 129, L. heterorhinum; 130, L. leucozonium. 131, L. fuscipenne, mesoscutum. 132, L. sisymbrii, abdomen showing basal hair band on tergum I. 133, L. coriaceum, abdomen showing lack of basal hair band on tergum 1. 134, L. leucozonium, head. 135, L. olympiae, head. 136, L. zonulum, mesoscutum. 137, L. olympiae, mesoscutum. 138, L. zonulum, tergum 1. 139, L. leucozonium, tergum 1; 140, vertex showing transverse striations behind ocelli. 141, L. zonulum, pronotal lateral angle. 142, L. timberlakei, mesoscutum. 143, L. olympiae, mesoscutum; 144, propodeum. 145, L. pacificum, propodeum. 146,

L. olympiae, pleuron dorsad of middle coxa. 147, L. pacificum, pleuron dorsad of middle coxa. 148, L. heterorhinum, pronotum, lateral view. 149, L. egregium, pronotum, lateral view. 150, L. manitouellum, mesoscutum. 151, L. anhypops, mesoscutum. 152, L. manitouellum, forewing. 153, L. mellipes, forewing. 154, L. anhypops, lateral edge of tergum II. 155, L. mellipes, lateral edge of tergum II.

## Key to Lasioglossum Females South of the Mexican Border

156, L. morrilli, acarinarium at base of tergum I. 157, L. desertum, acarinarium. 158, L. morrilli, head. 159, L. pallicorne, head. 160, L. egregium, pronotum, lateral view. 161, L. pallicorne, pronotum, lateral view; 162, acarinarium. 163, L. parkeri, acarinarium. 164, L. jubatum, dorsal propodeal surface. 165, L. acarophilum, dorsal propodeal surface. 166, L. jubatum, head. 167, L. acarophilum, head; 168, mesoscutum. 169, L. uyacicola, mesoscutum. 170, L. argutum, dorsal propodeal surface. 171, L. cercothrix, dorsal propodeal surface. 172, L. argutum, head. 173, L. circinatum, head. 174, L. tropidonotum, head and thorax. 175, L. circinatum, mesoscutum. 176, L. pharum, mesoscutum. 177, L. eickworti, forewing. 178, L. manitouellum, forewing. 179, L. perscabrum, dorsal propodeal surface. 180, L. orphnaeum, dorsal propodeal surface; 181, mesoscutum; 182, pronotum, lateral view. 183, L. pallicorne, head. 184, L. transvorsum, head; 185, dorsal propodeal surface. 186, L. asaphes, dorsal propodeal surface. 187, L. aequatum, dorsal propodeal surface. 188, L. manitouellum, dorsal propodeal surface.

## Key to Lasioglossum Males North of the Mexican Border

189, L. fuscipenne, male sternal vestiture; 190, female mesoscutum (only female photographs were taken in cases where the sexes were similar for certain features). 191, L. olympiae, female dorsal propodeal surface. 192, L. titusi, female dorsal propodeal surface. 193, L. heterorhinum, female dorsal propodeal surface. 194, L. sisymbrii, female abdomen showing

basal hair band on tergum I. 195, L. coriaceum, female abdomen. 196, L. leucozonium, female vertex, dorsal view. 197, L. titusi, female vertex, dorsal view; 198, male sternal vestiture. 199, L. pacificum, head. 200, L. zonulum, head. 201, L. pacificum, male sternal vestiture. 202, L. timberlakei, male sternal vestiture. 203, L. olympiae, male sternal vestiture. 204, L. leucozonium, male sternal vestiture. 205, L. zonulum, male sternal vestiture. 206, L. coriaceum, head. 207, L. mellipes, head. 208, L. channelense, head. 209, L. lampronotum, head. Male sternal vestiture: 210, L. heterorhinum; 211, L. jubatum; 212, L. athabascense; 213, L. mellipes; 214, L. desertum. 215, L. athabascense, head. 216, L. trizonatum, head. 217, L. athabascense, gonostylus. 218, L. trizonatum, gonostylus; 219, antenna showing circular tyli. 220, L. egregium, antenna (without tyli). 221, L. mellipes,

male vestiture. 222, L. forbesii, male vestiture. 223, L. paraforbesii, head. 224, L. forbesii, head. Male sternal vestiture: 225, L. acarophilum; 226, L. desertum; 227, L. manitouellum. 228, L. sisymbrii, forewing. 229, L. manitouellum, forewing. Heads: 230, L. colatum; 231, L. anhypops; 232, L. trizonatum. Gonostyli: 233, L. morrilli; 234, L. anhypops.

#### Key to Lasioglossum Males South of the Mexican Border

235, L. eickworti, forewing; 236, head. Male sternal vestiture: 237, L. tricnicos; 238, L. crocoturum; 239, L. jubatum; 240, L. heterorhinum; 241, L. pallicorne; 242, L. asaphes; 243, L. cercothrix; 244, L. costale.

#### REQUIREMENTS FOR SMITHSONIAN SERIES PUBLICATION

Manuscripts intended for series publication receive substantive review (conducted by their originating Smithsonian museums or offices) and are submitted to the Smithsonian Institution Press with Form SI-36, which must show the approval of the appropriate authority designated by the sponsoring organizational unit. Requests for special treatment—use of color, foldouts, case-bound covers, etc.—require, on the same form, the added approval of the sponsoring authority.

**Review** of manuscripts and art by the Press for requirements of series format and style, completeness and clarity of copy, and arrangement of all material, as outlined below, will govern, within the judgment of the Press, acceptance or rejection of manuscripts and art.

Copy must be prepared on typewriter or word processor, double-spaced, on one side of standard white bond paper (not erasable), with 1¼" margins, submitted as ribbon copy (not carbon or xerox), in loose sheets (not stapled or bound), and accompanied by original art. Minimum acceptable length is 30 pages.

Front matter (preceding the text) should include: title page with only title and author and no other information, abstract page with author, title, series, etc., following the established format; table of contents with indents reflecting the hierarchy of heads in the paper; also, foreword and/or preface, if appropriate.

First page of text should carry the title and author at the top of the page; second page should have only the author's name and professional mailing address, to be used as an unnumbered footnote on the first page of printed text.

Center heads of whatever level should be typed with initial caps of major words, with extra space above and below the head, but no other preparation (such as all caps or underline, except for the underline necessary for generic and specific epithets). Run-in paragraph heads should use period/dashes or colons as necessary.

**Tabulations** within text (lists of data, often in parallel columns) can be typed on the text page where they occur, but they should not contain rules or numbered table captions.

Formal tables (numbered, with captions, boxheads, stubs, rules) should be submitted as carefully typed, double-spaced copy separate from the text; they will be typeset unless otherwise requested. If camera-copy use is anticipated, do not draw rules on manuscript copy.

**Taxonomic keys** in natural history papers should use the aligned-couplet form for zoology and may use the multi-level indent form for botany. If cross referencing is required between key and text, do not include page references within the key, but number the keyed-out taxa, using the same numbers with their corresponding heads in the text.

**Synonymy** in zoology must use the short form (taxon, author, year:page), with full reference at the end of the paper under "Literature Cited." For botany, the long form (taxon, author, abbreviated journal or book title, volume, page, year, with no reference in "Literature Cited") is optional.

**Text-reference system** (author, year:page used within the text, with full citation in "Literature Cited" at the end of the text) must be used in place of bibliographic footnotes in all Contributions Series and is strongly recommended in the Studies Series: "(Jones, 1910:122)" or "... Jones (1910:122)." If bibliographic

footnotes are required, use the short form (author, brief title, page) with the full citation in the bibliography.

Footnotes, when few in number, whether annotative or bibliographic, should be typed on separate sheets and inserted immediately after the text pages on which the references occur. Extensive notes must be gathered together and placed at the end of the text in a notes section.

Bibliography, depending upon use, is termed "Literature Cited," "References," or "Bibliography." Spell out titles of books, articles, journals, and monographic series. For book and article titles use sentence-style capitalization according to the rules of the language employed (exception: capitalize all major words in English). For journal and series titles, capitalize the initial word and all subsequent words except articles, conjunctions, and prepositions. Transliterate languages that use a non-Roman alphabet according to the Library of Congress system. Underline (for italics) titles of journals and series and titles of books that are not part of a series. Use the parentheses/colon system for volume (number): pagination: "10(2):5–9." For alignment and arrangement of elements, follow the format of recent publications in the series for which the manuscript is intended. Guidelines for preparing bibliography may be secured from Series Section, SI Press.

Legends for illustrations must be submitted at the end of the manuscript, with as many legends typed, double-spaced, to a page as convenient.

Illustrations must be submitted as original art (not copies) accompanying, but separate from, the manuscript. Guidelines for preparing art may be secured from Series Section, SI Press. All types of illustrations (photographs, line drawings, maps, etc.) may be intermixed throughout the printed text. They should be termed Figures and should be numbered consecutively as they will appear in the monograph. If several illustrations are treated as components of a single composite figure, they should be designated by lowercase italic letters on the illustration; also, in the legend and in text references the italic letters (underlined in copy) should be used: "Figure 9b." Illustrations that are intended to follow the printed text may be termed Plates, and any components should be similarly lettered and referenced: "Plate 9b." Keys to any symbols within an illustration should appear on the art rather than in the legend.

Some points of style: Do not use periods after such abbreviations as "mm, ft, USNM, NNE." Spell out numbers "one" through "nine" in expository text, but use digits in all other cases if possible. Use of the metric system of measurement is preferable; where use of the English system is unavoidable, supply metric equivalents in parentheses. Use the decimal system for precise measurements and relationships, common fractions for approximations. Use day/month/year sequence for dates: "9 April 1976." For months in tabular listings or data sections, use three-letter abbreviations with no periods: "Jan, Mar, Jun," etc. Omit space between initials of a personal name: "J.B. Jones."

Arrange and paginate sequentially every sheet of manuscript in the following order: (1) title page, (2) abstract, (3) contents, (4) foreword and/or preface, (5) text, (6) appendixes, (7) notes section, (8) glossary, (9) bibliography, (10) legends, (11) tables. Index copy may be submitted at page proof stage, but plans for an index should be indicated when manuscript is submitted.
