DESCRIPTION OF A NEW SPECIES OF THYRSITOPS (T. VIOLACEUS) FROM THE FISHING-BANKS OFF THE NEW ENGLAND COAST.

By TARLETON II. BEAN.

On the 7th of November, 1887, the National Museum received from Mr. W. A. Wilcox, agent of the U. S. Fish Commission at Gloucester, Mass., two fresh fishes, a Blue Chimæra, C. affinis, and a species of Thyrsitops, which does not appear to agree with any of the described species. The latter was caught by Capt. Thomas Thompson, schooner M. A. Baston, on Le Have Bank, in 125 fathoms.

The Thyrsitops is number 39287 of the fish register. It is 44 inches long to the base of the middle caudal rays. It is more nearly related to lepidopoides than to any other species; in fact, it is not very closely related to any of the others. If we may trust the figures and descriptions of T. lepidopoides our new species has a larger number of dorsal spines and rays and a much smaller number of dorsal and anal finlets. T. lepidopoides is said to be uniform silvery, the back somewhat plumbeous and the fins gray. Our species is uniformly purplish brown, the spinous dorsal, pectorals, ventrals, and inside of the mouth blackish.

The body is stout, its greatest width being exactly one-half of the height at the anal origin. The greatest height of the body is one-half of the length of the head, and is contained 8 times in the total length without caudal. The length of the head is one-fourth of the standard length; its greatest width is contained 41 times in its length. The width of the interorbital area is slightly greater than the length of the eye, which is contained nearly 75 times in the length of the head and 35 times in the length of the upper jaw. The least height of the tail equals the width of the interorbital area. The length of the snout equals twice the length of the longest dorsal spine, and one-half the distance from the tip of the snout to the origin of the spinous dorsal. The maxilla extends to the vertical through the front of the eye. The length of the upper jaw equals 31 times the width of the interorbital space. The mandible reaches to the vertical through the hind margin of the eye; its length, including the fleshy tip, is 5 times the width of the interorbital area The anterior nostril is smaller than the posterior; it is situated in advance of the eye one diameter of the eye. The posterior nostril is a narrow slit placed midway between the anterior and the eye. Strong teeth on the intermaxillary and mandible. Three large fangs anteriorly in the roof of the mouth; pseudobranchiæ well developed; no trace of gill-rakers. The spinous dorsal begins at a distance from the snout, which equals twice the length of the snout; it is highest in the middle. The ninth and thirteenth spines are slightly longer than the third spine and more than twice as long as the twentieth, their length equaling one-half that of the snout. The soft dorsal is highest anteriorly, its longest ray, the fifth, being nearly twice the least height of the tail. The caudal is forked; its middle rays about one-half as long as the external

Proc. N. M. 87——33

rays. The anal origin is under the third ray of the soft dorsal, its distance from the vent 2½ times the length of the dagger-shaped spine. The vent is directly under the end of the spinous dorsal. The anal rays are longest anteriorly, the fifth ray being nearly as long as the corresponding ray of the soft dorsal. The dagger-shaped spine in front of the anal equals one-half the least height of the tail. The ventral is immediately under the third spine of dorsal; its first and longest ray equals three-fourths of the interorbital width. The fifth ray is about two-thirds as long as the first. The pectoral begins under the second dorsal spine; its length equals 2½ times the width of the interorbital area. It extends to the vertical midway between the fifth and sixth dorsal spines.

The lateral line is well developed; it descends gradually from the upper angle of the gill opening, reaching the median line of the body under the soft dorsal. The scales are irregular in shape, thin, elongate, cycloid, and deciduous.

Color, purplish. The spinous dorsal, pectorals, ventrals, and inside of mouth blackish.

D. XX, 1, 19 + 2 finlets; A. 17 + 3 finlets; V. I., 5; p. 13.

TABLE OF MEASUREMENTS.	mm.
Length to base of caudal (44 inches)	1115
Greatest height of body	138
Height at ventrals	126
Height at anal origin	112
Least height of tail	40
Greatest width of body	56
Length of head	280
Greatest width of head	62
Width of interorbital area	40
Length of snout	117
Length of upper jaw	130
Length of mandible, with tip	203
Length of mandibular tip	23
Length of eye	37
Spinous dorsal, from tip of snout	233
Length of third dorsal spine	55
Length of ninth dorsal spine	58
Length of thirteenth dorsal spine	58
Length of twentieth dorsal spine	25
Length of fifth dorsal ray	78
Length of last dorsal ray	20
Length of second dorsal finlet	28
Caudal, length of middle rays	58
Caudal, length of external rays	116
Pectoral, from tip of snout	255
Length of pectoral	100
Ventral, from tip of snont	255 30
Length of first ventral ray	22
Length of fifth ventral ray	32
Length of dagger-shaped spine	20
Anal, from vent	45
Length of fifth anal ray	72
Length of last anal ray	20
Length of last anal finlet	28
